EXECUTIVE SUMMARY

The City of Ann Arbor Downtown Development Authority (DDA) has developed a Healthy Streets program intended to create a connected network of streets which provide safe and equitable mobility for all users, particularly in the downtown area. During the Healthy Streets pilot project that took place as part of the DDA's People Friendly Streets program from July to November of 2020, a temporary two-way separated bikeway was added on the east side of State Street. Based on the success of the project, conceptual plans were developed by Smithgroup for a permanent bikeway on State Street. Within the downtown, the State Street corridor between Washington Street at the north and Willian to the south has been selected for a corridor-wide operational investigation as described in the present report in order to assist in the design of the road and bikeway. The report analyzes and presents the operational impacts and proposes adjustments in geometry and operations to meet the needs of the proposed People Friendly Streets design changes for the following intersections in the project area:

- Washington Street and State Street
- Liberty Street and State Street
- North University Avenue and State Street
- William Street and State Street

The intersections of I-94 BL (Huron Street) at State Street just north of the project limits and South University Avenue at State Street just south of the project limits were included in the Synchro modeling to evaluate whether the proposed changes to traffic conditions impact operations to adjacent intersections within the project limits.

The State Street study corridor was analyzed for the morning and afternoon peak hours for the following conditions:

- Proposed Build Conditions
- Mitigated Build Conditions
- Alternative Build Conditions

The elements to be covered in the operational investigation were discussed with the DDA prior to the study commencing. A comprehensive crash analysis for the State Street study corridor was also completed and is attached in **Appendix B.** On the State Street corridor during the five-year study period, it was found that safety is of particular concern for nonmotorized users, as 5 of the 8 pedestrian and bicycle crashes involved injury (62.5 percent). The Crash Modification Factors for the proposed safety treatments at the four intersections including addition of the two-way protected bike lanes, other traffic calming measures, and modifying signal phasing are expected to reduce corridor-wide total crashes and have a positive safety impact.

Proposed Conditions

The proposed People Friendly design changes to the State Street corridor are as follows:

- Construct parking bump-outs on each side of State Street between Washington Street and William Street
- Turn-lane removals between Liberty Street and William Street
 - o Remove northbound left-turn lane on State Street at Liberty Street
 - Remove northbound right-turn lane on State Street at North University Avenue
- Replace exclusive right- and left-turn lanes on the North University Avenue approach to State Street
- Shared bicyclist and pedestrian "sidepath" along the east side of State Street between William Street and North University Avenue
- Implement bi-directional bikeway crossing east / west on the north side of William Street and State Street intersection

The existing weekday counts for the study intersections were provided by the City of Ann Arbor and were collected in November 2019 prior to the COVID pandemic. Based on the turning movement counts, the morning peak hour on the State Street study corridor was found to generally occur between the hour of 8:00 a.m. and 9:00 a.m. while the afternoon peak hour was found to occur between the hour of 4:45 p.m. and 5:45 p.m. These two time periods were selected for analysis of Proposed conditions.

The capacity analysis for Proposed conditions revealed that all study area intersections and approaches will operate at an acceptable level of service (LOS) for vehicles, pedestrians, and bicycles during both the weekday morning and weekday afternoon peak hours. Thus, all proposed People Friendly Streets design modifications are recommended with operational adjustments as recommended as part of this study.

Mitigated Build Conditions

While the results of the capacity analysis for Proposed conditions determined that all intersections and approaches will operate at an acceptable LOS for vehicles, pedestrians, and bicycles, traffic microsimulation analysis determined that queuing will be expected on the State Street approaches to the intersections. Thus, minor adjustments to signal timing phase splits and offsets were pursued to mitigate the queuing and improve progression along the study corridor. The AM and PM Peak hour cycle length remained at 90 seconds at each intersection under the Mitigated conditions operational analysis. The signal timing adjustments to accommodate the geometric changes were found to maintain similar overall intersection LOS for motor vehicles and at every signalized intersection within the study corridor during both peak hours. In addition, walking and biking delays were estimated in the traffic models which indicated that pedestrians are expected to operate at LOS B and bicycling at LOS B or LOSC for all movements during peak hours. Thus, the study recommends adjusting the signal timing at the study intersections to reflect the design changes.

Alternative Build Conditions

In discussions with the project team consisting of the Ann Arbor DDA, city of Ann Arbor engineering, Smithgroup, Wade Trim and Toole Design, three alternative design alternatives were selected for investigation. These alternatives include:

- 1. Converting the signalized intersections of Liberty Street at State Street and North University Avenue at State Street to stop-control on each intersection approach.
- 2. Implementing an exclusive pedestrian phase (EPP) to the intersections of Liberty Street, North University Avenue, and William Street at State Street, to operate all day except when the signals are running in nighttime Flash mode.
- 3. Removing all intersection traffic control at the intersections of Liberty Street and North University Avenue at State Street.
- 4. Retain dedicated right-turn lane along northbound State Street on approach to North University Avenue

The three-way stop-control alternative was found to result in excessive queues on all intersection approaches at Liberty Street and North University Avenue, particularly during the PM Peak hour. The queues on State Street were found to spillback beyond adjacent intersections resulting in unacceptable vehicle delay mainly attributed to the very large volumes of pedestrians crossing per hour at the intersection. A signal warrant analysis was performed for each intersection and determined that both intersections meet the criteria for signalization as required by vehicular volumes and pedestrian volumes. Thus, converting the intersections of Liberty Street and State and North University Avenue at State Street to three-way stop-control is not recommended.

Implementing an exclusive pedestrian phase in addition to the existing WALK indications at the intersections of Liberty Street, North University Avenue, and William Street at State Street was found to provide acceptable intersection LOS for vehicles, pedestrians and bicycles at each intersection during both the AM and PM Peak hours. Given that the observed traffic and multimodal volumes are highest during the AM and PM Peak hours, it was found that the exclusive pedestrian phase in combination with WALK phases will operate satisfactorily (with lower vehicle delays) during all other daily hours under normal signal operation. The exclusive pedestrian phase and WALK phases would not be present during nighttime Flash operation.

Due to the existing crash pattern related to vehicles turning right on red and pedestrian and bicycle movement conflicts, it is also recommended to prohibit right-turns on red during the exclusive pedestrian phase only. This can be accomplished via the installation of R10-11 "No Turn on Red" signs at the intersections. It was discussed by the project team to test this operation by implementing the timing changes to the signal controllers, and then conducting an evaluation on traffic safety and operations for a period of time.

Traffic microsimulation analysis determined that removing all traffic control at the intersections of Liberty Street and North University Avenue at State Street would in effect operate very similarly to the three-way stop-control alternative due to high pedestrian utilization at the intersections. Thus, the removal of all traffic control at the intersections is not recommended.

Retaining the dedicated northbound right-turn lane on State Street on approach to North University Avenue is expected to provide only marginal operational benefit at the intersection, and thus the study finds it feasible to provide space for the proposed bikeway by removing the right-turn lane as proposed in the People Friendly Streets design.

1.0 INTRODUCTION

In partnership with Smithgroup and the Ann Arbor Downtown Development Authority (DDA), Wade Trim has conducted a traffic operational analysis to investigate capacity issues due to the proposed roadway and traffic design changes on State Street. As shown in **Figure 1-1**, the geometric design changes on the State Street study corridor stretches from Washington Street to William Street. Additional adjacent intersections at Huron Street and South University Avenue are included in the Synchro modeling to evaluate whether there are operational impacts to the adjacent network. This report presents the results of the operational analyses conducted along the study corridor. Following a description of the methodology and data collection, this study includes a narrative of the existing and proposed conditions, a crash and safety analysis, issues relating to human factors, and a capacity analysis. A summary of recommendations is presented in the final section of the report.

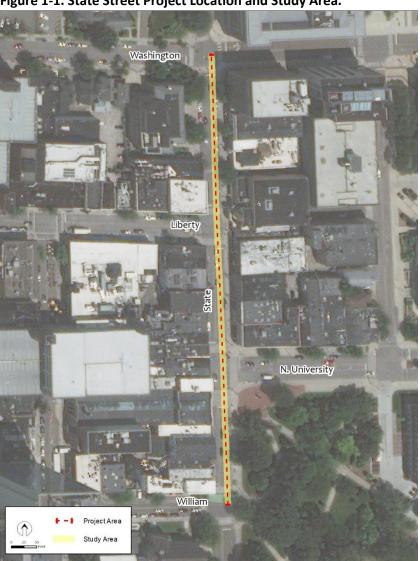

Figure 1-1. State Street Project Location and Study Area.

1.1 OBJECTIVE

The objective of this study was to conduct a comprehensive investigation into the operational effects resulting from the proposed People Friendly Streets infrastructure changes on the State Street corridor in the City of Ann Arbor. A Healthy Streets Pilot Project was conducted in 2020, and a report was developed that recommended further evaluation of the proposed changes to improve safety and operations on the corridor. This study evaluates the proposed geometric alternatives, as well as new operational alternatives developed as part of the Wade Trim analysis. A comprehensive operational investigation was conducted for each major intersection to determine the need for road design improvements based on crash history, geometric and human factors deficiencies, operational issues, and land development in the area.

2.0 METHODOLOGY AND DATA COLLECTION

This section of the report describes the methodology and analytical procedures that were used to identify and analyze operational conditions on the State Street study corridor. The investigation consisted of several phases including data collection, geometric and human factors analysis, capacity analysis and recommendations. A brief overview of the data collected for the study is given in the following paragraphs.

2.1 DATA COLLECTION

To accomplish the study objectives, the work effort involved the collection of data pertaining to roadway geometry, traffic counts and turning movements, and traffic control information, as well as other field data such as posted traffic regulations and observations of driver behavior. A discussion of the data collection procedure and analysis of the data is presented in subsequent sections of this report.

2.1.1 Existing Roadway Geometry

The existing roadway geometry for the study area was obtained from historical survey, existing plans, and aerial photos. These resources were supplemented by field reviews of the study area by the project team to verify lane widths, intersection configuration, turning radii, lane usage, and other roadway features.

2.1.2 Intersection Turning Movement Counts and Traffic Volume Counts

Directional turning movement counts for the study intersections were collected by Mannik Smith Group on Thursday, November 7, 2019 while local schools were in session and prior to the COVID-19 pandemic response. The turning movement counts were furnished by the City of Ann Arbor for use in the study. Truck volumes and the number of pedestrians crossing the roadway were also recorded. The counts were conducted during the AM, mid-day, and PM hours. For the purposes of this project, AM Peak and PM Peak hours were examined. The time of the peak hours varied by intersection but were generally found to adhere to the following patterns. On State Street, the AM Peak hour was typically between 8:00 and 9:00 AM and the PM Peak hour was typically between 4:45 and 5:45 PM. These data were used in the intersection capacity analyses as well as in the other study processes. Summary reports of the count data used in the analysis are attached in **Appendix A**.

2.2 GEOMETRIC ANALYSIS AND HUMAN FACTORS ANALYSIS

2.2.1 Quantitative Intersection Analyses

Quantitative intersection analyses were conducted to identify safety, geometric, capacity, and other design deficiencies at the study intersections. The procedures used to conduct the analyses are each briefly described in the following paragraphs.

2.2.2 Crash Analysis

A comprehensive crash analysis for the State Street study corridor was completed and is attached in **Appendix B.** This analysis was conducted to identify any abnormally high crash characteristics such as collision type, severity, environmental conditions, contributing factors, and other crash features at the study intersections. The crash analysis involved conducting a review of the characteristics for the crashes within the study area. The data were quantified by characterizing the crashes by location, type of collision (such as rear end, angle, pedestrian, etc.), severity, and environmental conditions. Crash Modification Factors (CMFs) were used to determine the expected change in crashes resulting from the Healthy Streets design modifications. The results of the crash analysis were used during the capacity analysis.

On the State Street corridor from Washington Street to William Street, there were a total of 115 crashes reported during the five-year study period (2016-2020). No crashes were reported which resulted in a Type A injury or fatality. However, 3 Type B, and 8 Type C injury crashes occurred along the corridor. The predominate crash types involved either a sideswipe – same direction collision, rear end, or backing collision. There were 4 crashes involving a bicyclist and 4 crashes involving a pedestrian. 5 of the 8 bicyclist and pedestrian crashes reported at least one injury (62.5 percent). The CMFs for the proposed safety treatments at the four intersections including addition of the two-way protected bike lanes, other traffic calming measures, and modifying signal phasing are expected to reduce corridor-wide total crashes by 7.35 crashes per year.

2.2.3 Geometric Analysis and Human Factors Analysis

A geometric analysis was conducted for the purpose of reviewing the proposed roadway geometry to ensure that it will operate an acceptable Level of Service (LOS) for vehicles, pedestrians and bicycles, and to determine whether any adjustments were needed to the design.

A thorough field study of existing conditions at the intersections and the surrounding areas was conducted. Existing conditions were compared with safety guidelines and design standards, including the 2012 Michigan Manual on Uniform Traffic Control Devices (MMUTCD), the 2018 American Association of State Highway and Transportation Officials (AASHTO) Policy on Geometric Design of Highways and Streets, and other MDOT traffic standards and design notes.

A human factors analysis was also conducted to observe driver behavior and examine the relationship between existing geometric and traffic control conditions and safety performance. This analysis included observation of vehicle approach speeds; directional, warning, and regulatory signing; pavement marking usage; violations of driver expectancy; and landscaping from the perspective of the driver.

2.2.4 Intersection Capacity Analysis

The software package Synchro 11 was used to conduct intersection analyses for proposed roadway conditions. Synchro 11 is a software used for modeling and optimizing traffic signal timing at intersections. The program utilizes the methods of the *Highway Capacity Manuals 2000* to calculate capacity. Although newer versions of the Highway Capacity Manual are available, the intersection and/or signal timing configurations for vehicles are not supported for LOS in the newer manuals. Pedestrian and Bicycle LOS was determined using the HCM 6th methodology at signalized intersections. The delay calculated in Synchro is average control delay, which is the same measure used to describe intersection operations in the *Highway Capacity Manual 2000* and related software (HCS). The key features and capabilities of Synchro include capacity analysis, coordination, actuated signals, and the development of time-space diagrams. The program optimizes the split, cycle length, and offsets to reduce delays.

Capacity analyses were conducted to measure the performance of intersections in terms of Level of Service (LOS). Levels of service range from A, which represents the best traffic condition, to F, which is the worst condition. Along with the LOS, intersection capacity is quantified in terms of average control delay, which is measured in seconds of delay per vehicle. Control delay includes the initial deceleration delay, queue move-up time, stopped delay, and acceleration delay. The vehicle level of service criteria for signalized intersections is given in **Table 2-1** and unsignalized in **Table 2-2**.

| Table 2-1. Vehic | le Level of Service Criteria for Signalized Intersections. | |
|---------------------|--|--------------------------------------|
| Level of Service | Description | Control Delay per vehicle in seconds |
| А | Little delay, favorable progression. | ≤ 10 |
| В | Low delay, good progression. | >10-20 |
| С | Average delay, fair progression. | >20-35 |
| D | Longer delay, unfavorable progression. | >35-55 |
| E | High delay, poor progression. | >55-80 |
| F | Unacceptable delay, very poor progression. | >80 |

Source: Transportation Research Board, Highway Capacity Manual 2000.

| Table 2-2. Vehicle | Table 2-2. Vehicle Level of Service Criteria for Unsignalized Intersections. | | | | | | | | | | |
|---------------------|--|--------------------------------------|--|--|--|--|--|--|--|--|--|
| Level of Service | Description | Control Delay per vehicle in seconds | | | | | | | | | |
| А | Little delay, favorable progression. | ≤ 10 | | | | | | | | | |
| В | Low delay, good progression. | >10-15 | | | | | | | | | |
| С | Average delay, fair progression. | >15-25 | | | | | | | | | |
| D | Longer delay, unfavorable progression. | >25-35 | | | | | | | | | |
| E | High delay, poor progression. | >35-50 | | | | | | | | | |
| F | Unacceptable delay, very poor progression. | >50 | | | | | | | | | |

Source: Transportation Research Board, Highway Capacity Manual 2000.

One important factor used in calculating capacity at intersections is the peak-hour factor. The peak-hour factor is found by dividing the total hourly volume observed on an approach leg by four times the highest 15-minute volume. As manual traffic counts based on 15-minute data were obtained for the intersections, the peak-hour factors used in the analyses are based on actual count data.

3.0 EXISTING AND PROPOSED DESIGN CONDITIONS

The Ann Arbor Downtown Development Authority (DDA) has proposed new bike lanes and other geometric changes on State Street. The purpose of this investigation is to determine whether the proposed changes will impact the corridor's level of service due to the removal of lanes and turn lanes.

3.1 EXISTING CONDITIONS

Within the Ann Arbor DDA, there is currently of mix of infrastructure designs that support bicyclists. Some stretches include bike lanes while other areas have sharrow pavement markings painted on the roadway. In addition, downtown Ann Arbor has a combination of two-way and one-way streets. These elements combine for a complex transportation system.

State Street is a north-south corridor in the downtown area of the City of Ann Arbor. The study section is approximately 0.17 miles and extends between Washington Street on the northern end and William St on the southern end. The speed limit on State Street in this area is 25 miles per hour.

The existing roadway geometric characteristics are as follows:

- The existing corridor consists of a two-lane cross section with one northbound land and one southbound lane.
- Between Huron Street and Washington Street, parking is available on the east side of the roadway, and northbound traffic has a left turn lane with a storage length of approximately 50 feet. The two-lane cross section continues from Washington Street to Liberty Street with parking on both sides of the roadway.
- Between Liberty Street and North University Avenue, parking is available on the west side of the roadway and northbound traffic has a left turn lane with a storage length of approximately 100 feet.
- Between North University Avenue and William Street, parking is available on the west side of the roadway and northbound traffic has a thru lane and a shared thru and right-turn lane with a storage length of approximately 50 feet.
- Between William Street and South University Avenue, parking available on both sides of the roadway and south bound traffic has a left turn lane with a storage length of approximately 50 feet.
- Northbound bike sharrow pavement markings are present on the roadway between Huron Street and Liberty Street.
- Southbound bike sharrow pavement markings are present between Huron Street and South University Avenue.

Land use along the State Street corridor is a mix of commercial, residential, and institutional land uses. Two church buildings are located along the corridor as well as a college dormitory. Multiple university buildings are present along the corridor, including academic buildings, a student union, and a university museum. Commercial uses include restaurants and shopping areas.

3.2 PROPOSED CONDITIONS

The proposed Healthy Street design roadway geometric characteristics are as follows:

- Parking bump-outs are proposed along State Street on the east and west sides of the roadway between Washington Street and William Street.
- On State Street between Washington Street and William Street, traffic will be configured to a two-lane cross section with one northbound lane and one southbound lane with no auxiliary turn lanes present.
- "Super Sharrow" pavement markings (or larger, lane-centered sharrows) will be installed between North University Avenue and William Street, where the bikeway will connect and continue onto North University Avenue.
- A shared bicyclist and pedestrian "sidepath" will be present along the east side of State Street between William Street and North University Avenue.
- A bi-directional bikeway will be installed crossing east / west on the north side of William Street and State Street intersection.
- The separate right- and left-turn lanes on the eastbound North University Avenue approach to State Street will be replaced with a single lane serving all movements.
- Directional protected bike lanes will be implemented on each side of the North University Avenue approach to State Street.
- Traffic calming such as raised intersections, curbless design, high visibility materials, reduced travel lane width will be implemented.

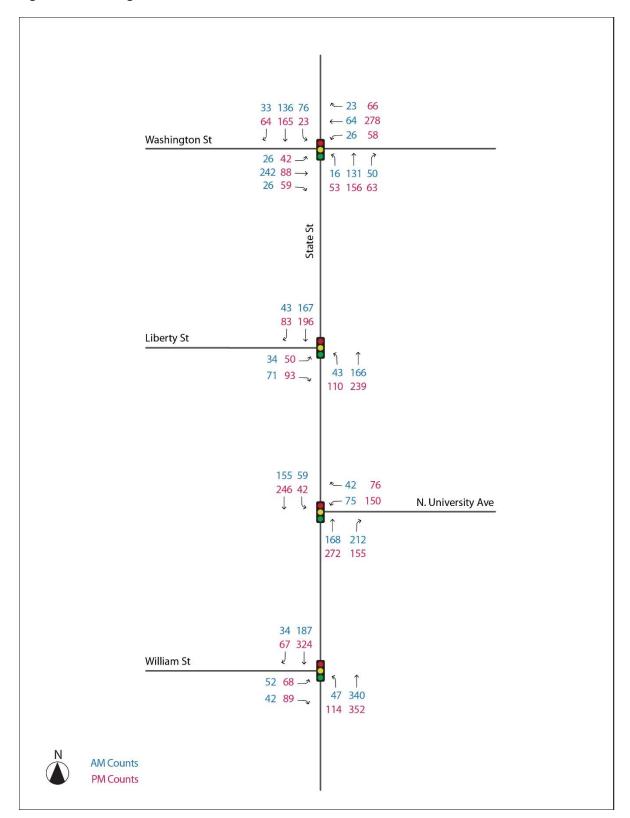

A conceptual exhibit which depicts these modifications is attached in Appendix C.

4.0 CAPACITY ANALYSIS

4.1 TRAFFIC VOLUME DATA

As previously mentioned in Section 2.1.2 of this report, the traffic counts were collected at various times and by various organizations over the past ten years. The time of the peak hours varied by intersection but were generally found to adhere to the following patterns. The AM Peak hour was typically between 8:00 and 9:00 AM and the PM Peak hour was typically between 4:45 and 5:45 PM. The AM Peak and PM Peak hour vehicle counts are shown in **Figure 4-1.** The AM Peak and PM Peak hour pedestrian and bicyclist counts are shown in **Figure 4-2**.

Figure 4-1. Existing Vehicle Traffic Volumes on State Street.

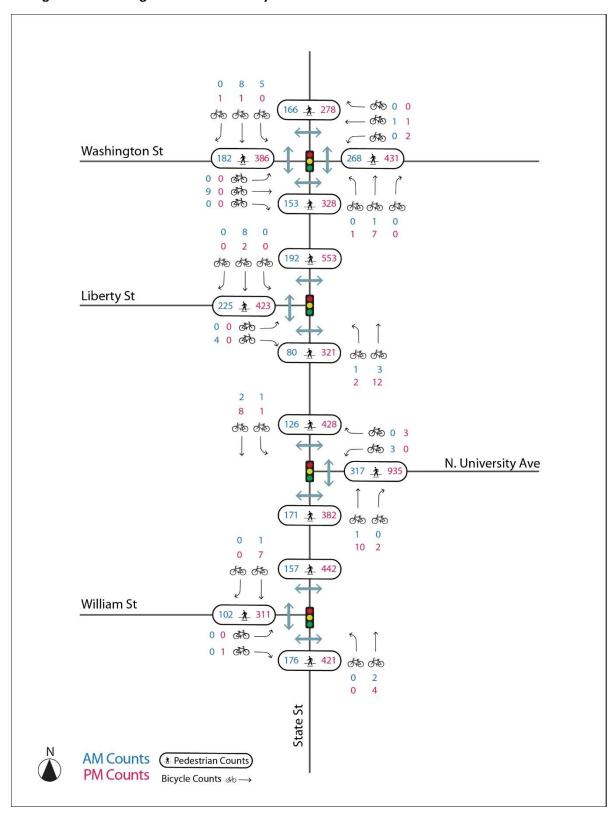

Figure 4-2. Existing Pedestrian and Bicyclist Traffic Volumes on State Street.

4.2 CAPACITY ANALYSIS OF PROPOSED AND MITIGATED CONDITIONS

The capacity analyses conducted for the Proposed conditions were based on the available traffic count information, current lane geometry, heavy vehicle usage, and existing signal timing. Signal timing changes were investigated to mitigate capacity deficiencies discovered during the analysis. A subsequent capacity analysis was conducted under Mitigated conditions. A summary of the results of the capacity analysis for the Proposed and Mitigated conditions on State Street follows.

4.2.1 Proposed Conditions

A summary of the vehicle delay and level of service (LOS) expected under Proposed conditions with geometric changes only on State Street is displayed in **Table 4-1**. As shown, all study intersections are expected to operate at acceptable LOS C or better for vehicles during the AM Peak and PM Peak hours. Additionally, all intersection approaches are likewise anticipated to operate at LOS D or better for vehicles during each of the Peak hours. The SimTraffic vehicle queuing results are depicted in **Table 4-2**. Vehicle capacity and queuing worksheets for Proposed conditions are included in **Appendix D**.

4.2.2 Mitigated Conditions

Corridor-wide signal timing changes were investigated to improve traffic operations at each intersection. The existing 90 second cycle length was maintained at each intersection on State Street. Minor adjustments were made to phase splits and offsets to improve total intersection LOS and coordination between intersections. Leading pedestrian intervals (LPIs) were included at the intersections of State Street at Liberty Street, North University Avenue, and William Street. Additionally, it is recommended to update the clearance intervals based on the final design. A summary of the vehicle delay and LOS expected under these Mitigated conditions is shown in **Table 4-3.** The SimTraffic queuing results are depicted in **Table 4-4**. As shown, relative to Proposed conditions, the signal timing adjustments tend to improve queuing on the northbound and southbound State Street approaches while increasing the queue lengths on the side-street approaches to the intersections.

Comparisons of vehicle delay and LOS between Proposed and Mitigated conditions are depicted in Figure 4-3 and Figure 4-4 for the AM Peak hour and in Figure 4-5 and Figure 4-6 for the PM Peak hour. As seen, the minor adjustments to signal timing to accommodate the geometric changes improved overall intersection LOS for vehicles compared to Proposed conditions at every signalized intersection during both peak hours. Vehicle capacity and queuing worksheets for Mitigated conditions are included in Appendix E.

Table 4-1. Capacity Results for Proposed Conditions on State Street.

4.2.3 Pedestrian and Bicycle Level of Service

Delay and level of service (LOS) as determined by the Highway Capacity Manual methodology represent quantitative measures of the adequacy of a facility to serve the operational needs of non-motorized users. The perceived quality of service of a facility for non-motorized users is also influenced by qualitative measures such as security, safety, grades, lighting, surface conditions, street activity levels, separation from vehicle traffic, speed of adjacent vehicles, frequency of heavy vehicles, provision of onstreet parking, and other factors. As qualitative measures, these indicators can be difficult to quantify, but most, if not all, are improved via the proposed changes in the People Friendly Streets design on State Street.

The traffic models produced in this analysis were used to determine anticipated pedestrian and bicycle level of service (LOS) in addition to vehicular LOS at signalized intersections (traffic models do not support nonmotorized pedestrian and bicycle results for all-way and two-way stop-controlled intersections). Synchro provides the functionality to report the delay and LOS expected by non-motorized users and was used to report these quantitative measures in the present study. A summary of the pedestrian and bicycle level of service (LOS) expected under Mitigated conditions at the signalized study intersections is displayed in **Table 4-5**. As shown, walking and biking delays were estimated in the traffic models which indicated that pedestrians are expected to operate at acceptable LOS B and bicycling at LOS B or LOS C for all movements during peak hours. Pedestrian and Bicycle LOS worksheets for Mitigated conditions are included in **Appendix F.**

4.3 CAPACITY ANALYSIS OF ALTERNATIVE CONDITIONS

In discussions with the project team consisting of the Ann Arbor DDA, City of Ann Arbor engineering, Smithgroup, Wade Trim and Toole Design, three alternative design alternatives were selected for investigation. These alternatives include:

- 1. Converting the signalized intersections of Liberty Street at State Street and North University Avenue at State Street to stop-control on each intersection approach.
- 2. Implementing an exclusive pedestrian phase to the intersections of Liberty Street and North University Avenue, and William Street at State Street, to operate all-day except when the signals are running in nighttime Flash mode.
- 3. Removing all intersection traffic control at the intersections of Liberty Street and North University Avenue at State Street.

4.3.1 Alternative One – Three-way Stop-Control

For the alternative which removes signalization and places each approach under stop-control at the intersections of Liberty Street and North University Avenue at State Street, two different lane configurations were explored:

- The first lane configuration is the conceptual design previously described in Section 3.2. of this report. With this design, all vehicle turning movements are served by a single approach.
- The second lane configuration is the same as the first, except the existing turn lanes are retained at the intersections.

A capacity analysis of each of these options was performed and the results are shown in **Table 4-5.** While the vehicle delay and corresponding LOS for each of the intersection approaches fall within the acceptable range, the SimTraffic analyses exhibited excessive queues on each approach – particularly during the PM Peak hour, which is mainly attributed to the very large volumes of pedestrians crossing per hour at the intersection. A signal warrant analysis was performed for each intersection and determined that both intersections meet the criteria for signalization as required by vehicular volumes and pedestrian volumes. The SimTraffic vehicle queuing results are depicted in **Table 4-6**. The vehicle capacity and queuing reports for the three-way stop-control alternative are included in **Appendix E.**

4.3.2 Alternative Two – Exclusive Pedestrian Signal Phasing

Implementing an exclusive pedestrian phase was investigated for operational performance at each of the intersections of Liberty Street at State Street, North University Avenue at State Street, and William Street at State Street. Conventionally, a pedestrian scramble phase prohibits vehicle movements from all approaches while only pedestrian movements are allowed. The duration of the Flashing Don't Walk (FDW) portion of the scramble phase is determined by the maximum crossing distance. The pedestrian scramble was evaluated but would require new pedestrian signal equipment which is not included in the scope of work for this project. In the exclusive pedestrian phase, pedestrians may cross perpendicular to the conflicting vehicle travel approach like normal.

A review was performed of criteria established by state and national transportation agencies for consideration of implementation of an exclusive pedestrian phase. While the criteria varied by agency, some of the measures included:

- FHWA PEDSAFE "Case Study No. 23 Exclusive Pedestrian Phasing"
 - Total pedestrian crossing volume should be preferably more than 1,000 pedestrians per hour during at least four hours a day
 - Vehicular volumes shall be moderate (recommended total intersection approach volume less than 2,000 vehicle per hour) and steady for many hours of the day with high percentage of left or right turns
 - o Vehicle volume peak times should coincide with pedestrian volume peak times
 - Intersections with existing level of service C or lower
- Boston Transportation Department "Boston Complete Streets Guidelines"
 - Conflicting turning vehicle volumes should be equal or greater than 250 vehicles per hour
 - Locations with restricted sight distance
 - Locations with complex intersection geometry
 - Locations near elderly housing, schools, recreational areas, medical facilities, or other facilities within a safety zone
- New York City DOT "Exclusive Pedestrian Signal Phase Treatments Study"
 - o "T"-intersection geometry is preferrable

Table 4-7 on the following page compares the intersections against these criteria. As seen, numerous criteria are met at each intersection.

Table 4-7. Comparison of Intersections against Exclusive Pedestrian Phasing Criteria.

| Measure | Libery Street @ State Street | N University Avenue @ State Street | William Street @ State Street | | |
|---|--|---|---|--|--|
| Total pedestrian crossing volume should be preferably more than 1,000 pedestrians per hour during at least four hours a day | Yes: 11 AM - 2 PM, 4 PM - 6 PM | Yes: 11 AM - 2 PM, 4 PM - 6 PM | No: 12 PM & 5 PM | | |
| Total intersection vehicle volumes less than 2,000 vehicles per hour (vph), with high percentage of left or right turns | Yes: All hours counted less than 2,000 vph (26% NB LT, 28% SB RT) | Yes: All hours counted less than 2,000 vph (40% NB RT, 16% SB LT) | Yes: All hours counted less than 2,000 vph (19% NB LT, 20% SB RT) | | |
| Vehicle volume peaks coincide with pedestrian volume peaks | Yes | Yes | Yes | | |
| Existing level of service C or worse | LOS B during AM & PM Peaks under mitigated conditions | LOS B during AM Peak, LOS C during PM Peak under mitigated conditions | LOS B during AM Peak, LOS C during PM Peak under mitigated conditions | | |
| Conflicting turning vehicle volumes equal or greater than 250 vehicles per hour | Yes | Yes | Yes | | |
| Location with restricted sight distance | No | No | No | | |
| Location with complex intersection geometry | Yes | Yes | Yes | | |
| Location near elderly housing, school, recreational area, medical facility, or other facility within a safety zone | Yes | Yes | Yes | | |
| "T"-Intersection geometry | Yes | Yes | Yes | | |

Given that the safety analysis indicated an existing crash pattern involving pedestrians being struck by vehicles performing right turns on red (RTOR), a modification to the exclusive pedestrian phase alternative was investigated whereby RTOR would be prohibited on all approaches. Additionally, retaining the existing exclusive right- and left-turn lanes on the North University Avenue approach was analyzed. A capacity analysis of the exclusive pedestrian phase alternative with, and without, these modifications was performed, and the results are shown in **Table 4-8.** The SimTraffic vehicle queuing results are depicted in **Table 4-9**, while the volume to capacity (V/C) ratios and upstream block time percentages at the intersections with RTOR restrictions are shown in **Table 4-10**. The vehicle capacity and queuing reports for the exclusive pedestrian phase alternative are included in **Appendix E.**

As seen in **Table 4-8**, each intersection is expected to operate at LOS C or better for vehicles during both peak hours for any of the various implementations of the exclusive pedestrian phase at the intersections. Acceptable LOS is maintained when prohibiting right-turns on red at any of the intersections, resulting in only minor increases to delay. Retaining the existing exclusive right- and left-turn lanes on the westbound North University Avenue approach would slightly improve delay at the intersection.

Table 4-8. Capacity Results for Exclusive Pedestrian Phasing on State Street at Liberty Street, North University Avenue, and William Street.

As shown in **Table 4-9**, relative to Proposed and Mitigated conditions, the exclusive pedestrian phase alternative is expected to increase queue lengths on each intersection approach on State Street. The table shows the 95th percentile queue length in feet for the right-turn and left-turn lanes at the study intersections. The 95th percentile queue is the maximum back of queue length that can accommodated by the 95th percentile of traffic volumes. This length is used to determine the length of the full-width storage lanes that should be available to accommodate the traffic demand. There are some roadway segments where 95th-percentile queue lengths may expect to exceed link lengths; however during the simulation of the entire peak hour, these queue lengths were infrequent and generally occurred during the peak 15-minute interval. Significantly shorter queue lengths are anticipated during most cycles of the peak hour and the majority of a typical day. The exhibited slight increases in traffic delays and queue lengths are a trade-off that is expected with the removal of the turn lanes for the proposed People-Friendly Streets design changes. Retaining the turn lanes on westbound North University Avenue is anticipated to reduce the queue lengths on the approach.

As shown in **Table 4-10**, the volume to capacity ratios are within the acceptable range, under 0.85 for urban intersections, at all approaches during each peak hour, except for the northbound State Street approach at William Street during the PM Peak hour (0.87). The percentage of upstream block time presented in **Table 4-10** indicates negligible likelihood of upstream intersections being blocked by vehicle queues at all intersection during each peak hour, except the southbound State Street approach to North University Avenue during the PM Peak hour. The 18% upstream block time indicates that the southbound queue may be expected to spill back to Liberty Street up to 7 of the 40 cycles during the PM Peak hour under a 90 second cycle length.

Table 4-10. V/C Ratios and Upstream Block Time Percentages for Exclusive Pedestrian Phasing on State Street, North University Avenue, and William Street.

| Intersection | Measure | | AM | Peak F | lour | | PM Peak Hour | | | | |
|--|------------------|------|------|--------|------|-------|--------------|------|------|------|-------|
| intersection | ivieasure | EB | WB | NB | SB | Total | EB | WB | NB | SB | Total |
| State Street and Liberty Street (EPP with No RTOR) | V/C | 0.52 | - | 0.31 | 0.32 | 0.30 | 0.49 | - | 0.61 | 0.37 | 0.46 |
| | Upstream Block % | 0% | - | 0% | 0% | n/a | 1% | ı | 0% | 3% | n/a |
| State Street and N. University Avenue (EPP with No RTOR) | V/C | 1 | 0.51 | 0.58 | 0.49 | 0.43 | ı | 0.77 | 0.68 | 0.57 | 0.54 |
| | Upstream Block % | - | 0% | 0% | 1% | n/a | ı | 0% | 7% | 18% | n/a |
| State Street and William Street (EPP with No RTOR) | V/C | 0.42 | - | 0.52 | 0.42 | 0.40 | 0.75 | 1 | 0.87 | 0.53 | 0.67 |
| | Upstream Block % | 0% | - | 0% | 0% | n/a | 0% | - | 1% | 1% | n/a |

As seen in **Table 4-8**, although implementation of no RTOR restrictions is expected to result in greater delays, particularly for the Liberty Street approaches, an acceptable LOS is expected to be maintained with no RTOR. While greater vehicle delays are expected due to the no RTOR restriction, queue lengths are marginally impacted by RTOR restrictions, as shown in **Table 4-9**.

Right turns on red at the intersection approaches may be prohibited via the installation of R10-11 "No Turn on Red" signs. It was discussed by the project team to test this operation by implementing the timing changes to the signal controllers and installing temporary R10-11 "No Turn on Red" signs.

Two viable strategies concerning the operation of an exclusive pedestrian phase (EPP) at the intersections are described below.

EPP Option 1 –EPP During the Daytime with Pedestrian Recall Overnight In this scenario, the intersection operates with pedestrian recall each cycle all day (no

pedestrian pushbutton actuation). The EPP runs during the day while the vehicle and pedestrian volumes are substantial and consistent, with EPP turned off overnight when pedestrian demand is diminished and set to flashing mode as it currently operates. If the flash mode were removed at the intersection, it could be set for pedestrian signal phasing to run concurrent with vehicle movement overnight.

• EPP Option 2 – Pushbutton Activation

Here the EPP operates with pedestrian recall each cycle during the majority of the day when pedestrian demand is substantial and steady but actuate the exclusive pedestrian phase via a pushbutton activation during times of day with diminished and/or more sporadic pedestrian demand.

It is recommended to introduce a pilot project for EPP Option 1 utilizing Pedestrian Recall with EPP During the Daytime. An ideal timeframe may be just prior to a new U of M semester in order for students to acclimate to the changes in traffic patterns. At the three study intersections, there would be insufficient benefit to installing the pushbuttons. With high pedestrian activity consistently throughout the day, pedestrians are present for each cycle to push the buttons and the EPP would likely be running with nearly all cycles.

Based on discussion with the City at the 1/18/22 State St signal meeting, in addition to an Exclusive Pedestrian Phase (EPP), further evaluation was conducted to determine whether the pedestrian phasing should operate concurrent with the associated vehicle phase to reduce the potential maximum delay that a pedestrian may experience at the intersection. This operation cannot be fully analyzed in Synchro as the conflicting peds are removed due to the EPP (the peds are no longer conflicting peds with vehicles). Due to this restriction, an estimated maximum delay was determined for the intersection of State Street and North University for comparison purposes and is shown in **Table 4-11**. The maximum delay a pedestrian may experience under signal operation with only an EPP is 70 seconds per pedestrian. The maximum delay a pedestrian may experience under signal operation with an EPP in addition to pedestrian phasing concurrent with vehicle phasing is 47 seconds per pedestrian (pedestrians crossing along State Street). Based on this data to reduce pedestrian delay and eliminate the potential conflict of pedestrians walking on a prolonged DO NOT WALK indication, it is recommended to include the concurrent WALK (recall) phases in addition to the EPP.

Table 4-11. Maximum Pedestrian Delay Comparison for North University Avenue at State Street

| Crosswalk | Pedestrians Crossing | Max Delay with EPP Only (sec/ped) | Max Delay with EPP & Concurrent WALK (sec/ped) | | |
|-----------------------------|----------------------|--------------------------------------|--|--|--|
| State St - South Leg | 382 | 70 | 47 | | |
| N University Ave - West Leg | 935 | 70 | 26 | | |
| State St - North Leg | 428 | 70 | 47 | | |

Time of Day Evaluation

The pedestrian crossing volumes exceed the 1,000 pedestrians per hour threshold for the four or more hours indicated in the table for the Liberty Street, N University and William intersections. A summary of the observed crossing pedestrian volumes for the AM, mid-day, and PM hours at each intersection is included below. While the crossing pedestrian volumes do not exceed 1,000 per hour during the AM hours, the volumes are still substantial, and it was considered operating the EPP during this time to provide consistent daily operation at the intersection.

Table 4-12. Total Pedestrians Crossing Intersections with Proposed Exclusive Pedestrian Phasing during AM Hours.

| Intersection | Total Pedestrians 7:00 – 8:00 AM | Total Pedestrians 8:00 – 9:00 AM |
|-----------------------------|-------------------------------------|-------------------------------------|
| N University Ave @ State St | 283 | 743 |
| Liberty St @ State St | 199 | 497 |
| William St @ State St | 183 | 524 |

Table 4-13. Total Pedestrians Crossing Intersections with Proposed Exclusive Pedestrian Phasing during Mid-Day Hours.

| Intersection | Total Pedestrians 10:00 – 11:00 AM | Total Pedestrians 11:00 – 12:00 PM | Total Pedestrians 12:00 – 1:00 PM | Total Pedestrians 1:00 – 2:00 PM |

| William St @ State St | No data available | 960 | 1073 | No data available |

Table 4-14. Total Pedestrians Crossing Intersections with Proposed Exclusive Pedestrian Phasing during PM Hours.

| Intersection | Total Pedestrians 4:00 – 5:00 PM | Total Pedestrians 5:00 – 6:00 PM |
|-----------------------------|-------------------------------------|-------------------------------------|
| N University Ave @ State St | 1601 | 1745 |
| Liberty St @ State St | 1313 | 1297 |
| William St @ State St | 884 | 1174 |

During the initial stage of the pilot project, the flash schedules can be set as they currently exist from midnight to 6:30 AM which coincides with other flash schedules at nearby intersections. This operation can then be evaluated and adjusted depending on the safety and operational outcomes of the pilot project. If it is found after the initial monitoring that the flash schedule should be modified or removed, the signal could be set for pedestrian signal phasing to run concurrent with vehicle movement overnight.

4.3.3 Alternative Three – Removal of All Intersection Traffic Control

An alternative which removes all intersection traffic control was explored at the intersections of Liberty Street and North University Avenue at State Street. The intention of this alternative is to remove all intersection traffic control devices and allow all users to negotiate priority at the intersection movement conflict points. Synchro software does not provide capacity outputs for uncontrolled intersections, so PTV Vissim traffic microsimulation software was used instead to analyze the traffic operations of the alternative. The preliminary simulation analysis determined that removing all forms of traffic control at the intersections would in effect operate very similarly to three-way stop-control, due to the robust pedestrian demand during the peak hours. Excessive vehicle queuing was exhibited on each intersection approach, particularly during the PM Peak hour.

4.3.4 Alternative Four – Northbound State Street Right Turn at North University Avenue

An analysis was performed to determine the impact of removing the northbound right-turn lane along State Street at North University Avenue. The build option under consideration in this analysis is the option which incorporates exclusive pedestrian phasing (EPP) with No Right Turns on Red and otherwise proposed geometry at the intersection. During analysis of Mitigated conditions as described in Section 4.2.2, signal timing adjustments were performed corridor-wide to provide more green time to the State Street approaches, thus minimizing additional delay otherwise expected by removal of the turn lanes along State Street at Liberty Street and North University Avenue. These signal timing adjustments were incorporated as a baseline in the analysis with the EPP at the intersection, with and without the northbound right-turn lane. The November 2019 traffic volumes were used in the analysis. The results of the capacity analyses are depicted in **Table 4-15**.

As seen, removal of the right turn late results in minor increases in delay during both the AM Peak and PM Peak hours for the State Street approaches at North University Avenue. All approach LOS values are expected to remain the same with removal of the right-turn lane, except for the southbound approach during the PM Peak hour (level of service falls from LOS B to LOS C with a 2.1 second increase in delay). The increase in delay to the southbound approach results from consolidation of the northbound through and right-turn movements to a single lane, thus reducing the frequency and duration of gaps for southbound left-turning traffic. Removing the turn lane does not change overall intersection LOS during either Peak hours.

Table 4-15. Capacity Results for Removal of Northbound Right-Turn Lane on State Street at North University Avenue.

| Intersection | Measure | | AM | Peak H | lour | | PM Peak Hour | | | | | | |
|---|-------------|----|------|--------|------|-------|--------------|------|------|------|-------|--|--|

5.0 FUTURE CONDITIONS

To analyze the feasibility of the Proposed, Mitigated, and Alternative Conditions under future traffic volumes, a background growth rate of 0.3% per year over 20 years was applied to the models. This background growth rate was obtained by consulting with the Washtenaw Area Transportation Study (WATS) model. A growth rate of 0.3% per year over 20 years results in a growth factor of 1.06.

5.1 FUTURE CAPACITY ANALYSIS OF PROPOSED AND MITIGATED CONDITIONS

A summary of the vehicle delay and LOS expected with future traffic volumes under Proposed conditions with geometric changes only is displayed in **Table 5-1**, while the queuing results are shown in **Table 5-2**. A summary of the vehicle delay and LOS expected with future traffic volumes under Mitigated conditions with signal timing adjustments is displayed in **Table 5-3**, while the queuing results are shown in **Table 5-4**.

As seen, all approaches are expected to continue operating at LOS C or better for vehicles during both the AM and PM Peak hours. Compared to the expected delay values under existing traffic volumes as shown in **Tables 4-1 and 4-3**, slight increases to delay are expected on each approach as a result of the increased traffic volumes. All approach and intersection vehicle LOS are expected to remain the same expect for those highlighted, where the increase in delay was large enough to exceed the previous LOS threshold. No LOS values increased larger than one letter grade threshold. As shown in **Tables 5-1** and **5-3**, the 95th percentile queue lengths are expected to increase on almost all intersection approach due to the increase in traffic volumes. The signal timing adjustments under Mitigated conditions tend to decrease the queue lengths on the State Street approaches, while increasing queue lengths on the side-street approaches.

5.2 FUTURE CAPACITY ANALYSIS OF EXCLUSIVE PEDESTRIAN PHASING ALTERNATIVE

A summary of the vehicle delay and LOS expected with future traffic volumes under the exclusive pedestrian phase alternative is displayed in **Table 5-5**. As seen, the approaches and overall intersections are expected to continue operating at LOS C or better for vehicles during both the AM and PM Peak hours, except for the intersection of William Street at State Street which is expected to operate at LOS D during the PM Peak hour with a LOS E (66.1 seconds / vehicle delay) on the eastbound approach. Given that the observed traffic volumes are highest during the AM and PM Peak hours, it is reasonable to ascertain that the exclusive pedestrian phase will operate satisfactorily (with lower vehicle delays) during all other daily hours under normal signal operation. The exclusive pedestrian phase would not be present during nighttime Flash operation. Pedestrian crosswalk LOS was indeterminate as the HCM 6e methodology does not support exclusive pedestrian phasing.

The approach and intersection vehicle LOS values are highlighted where the increase in delay was large enough to exceed the previous LOS threshold. No LOS values increased larger than one letter grade threshold. As shown in **Table 5-6**, queue lengths under future traffic volumes are expected to increase moderately on the approaches as a result of the no RTOR restrictions. Table 5-7 indicates that V/C ratios are expected to remain at or under the acceptable threshold of 0.85 except for the northbound State Street approach to William Street during the PM Peak hour, where the ratio is expected to increase by 0.07 compared to existing traffic volumes. Additionally, upstream block time percentages are expected to remain negligible to none during the AM Peak hour and negligible to moderate during the PM Peak hour (all approaches at or under 20% with most under 5%).

6.0 RECOMMENDATIONS

The following design changes are recommended for the State Street DDA corridor based on the findings of this operational study and the crash analysis report. Various corridor-wide as well as individual intersection improvements are recommended. On the State Street corridor during the five-year study period, it was found that safety is of particular concern for nonmotorized users, as 5 of the 8 pedestrian and bicycle crashes involved injury (62.5 percent). The Crash Modification Factors for the proposed safety treatments at the four intersections including addition of the two-way protected bike lanes, other traffic calming measures, and modifying signal phasing are expected to reduce corridor-wide total crashes by 7.35 crashes per year.

6.1 CORRIDOR-WIDE IMPROVEMENTS

Based on the results of the operational and crash analyses, the study recommends pursuit of each of the proposed People Friendly corridor design changes on State Street depicted in the conceptual exhibit attached in **Appendix C**. These design changes include:

- Parking bump-outs on each side of State Street between Washington Street and William Street
- Turn lane removals between Liberty Street and William Street
 - o Remove northbound left-turn lane on State Street at Liberty Street
 - o Remove northbound right-turn lane on State Street at North University Avenue
- Widened sidewalk along the east side of State Street between William Street and North University Avenue
- "Super Sharrow" pavement markings on State Street between William Street and North University Avenue to emphasize shared vehicle / bicycle use

In addition to these changes, minor adjustments to signal timing phase splits and offsets are recommended at each intersection to accommodate the design changes and improve traffic progression along the State Street corridor. These minor adjustments to signal timing are expected to improve intersection vehicle LOS while maintaining the existing 90 second cycle length along the corridor.

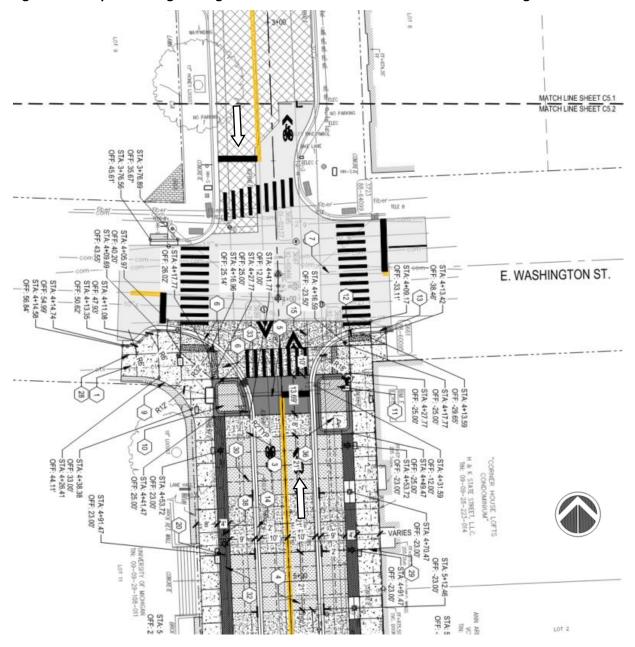

6.2 MAJOR INTERSECTION IMPROVEMENTS

6.2.1 State Street and East Washington Street

At the signalized intersection of State Street and East Washington Street, the study recommends implementing the proposed design changes as depicted in **Figure 6-1** and listed below:

• Construct parking bumpouts on both sides of the south leg of the intersection

Figure 6-1. Proposed Design Changes at Intersection of State Street and East Washington Street.

6.2.2 State Street and Liberty Street

At the signalized intersection of State Street and Liberty Street, the study recommends implementing the proposed design changes as depicted in **Figure 6-2** and listed below:

- Construct parking bumpouts on both sides of the north and south legs of the intersection
- Remove the northbound left-turn lane

The study additionally recommends implementing an exclusive pedestrian phase (EPP) to the signal timing operations. The study recommends that the City pursue EPP Option 1 as described in Section 4.3.2. While the signal is operating with an exclusive pedestrian phase, vehicle movements will be prohibited. To reduce pedestrian delay and eliminate the potential conflict of pedestrians walking on a prolonged DO NOT WALK indication, the concurrent WALK (recall) phases will remain. A R10-11 "No Turn on Red" sign should be installed facing the eastbound and southbound approaches. It was discussed by the project team to test this operation by implementing the timing changes to the signal controllers and installing temporary R10-11 "No Turn on Red" signs. The test case will allow the City to conduct an evaluation on traffic safety and operations for a period of time and make adjustments as necessary. Preliminary analysis determined that the signalized intersection would operate optimally at the following phase splits:

- 90 Second Cycle Length (AM Peak and PM Peak)
 - o Exclusive Pedestrian Phase: 20 Seconds in AM Peak and PM Peak
 - State Street Phase: 50 Seconds in AM Peak; 48 Seconds in PM Peak
 - o Liberty Street Phase: 20 Seconds in AM Peak; 22 Seconds in PM Peak

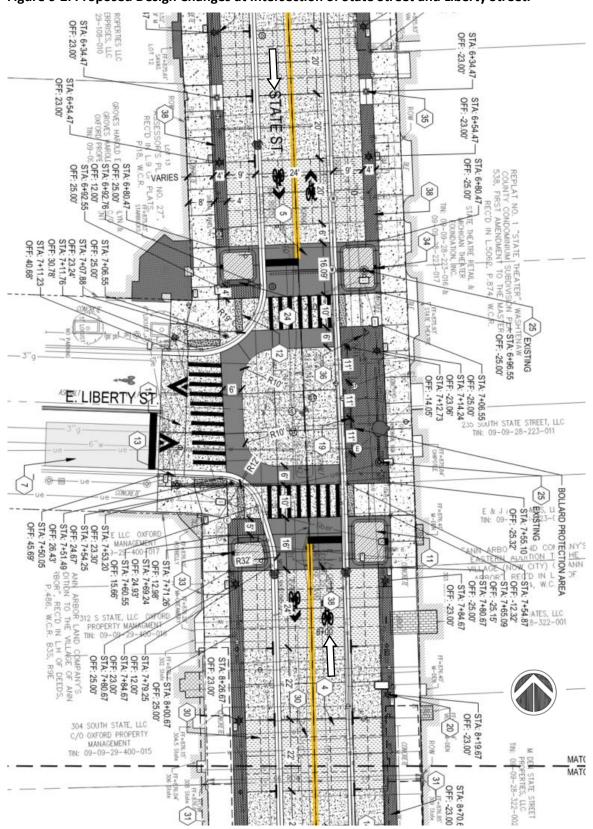

Figure 6-2. Proposed Design Changes at Intersection of State Street and Liberty Street.

6.2.3 State Street and North University Avenue

At the signalized intersection of State Street and North University Avenue, the study recommends implementing the proposed design changes as depicted in **Figure 6-3** and listed below:

- Replace the exclusive right- and left-turn lanes on the east leg with a single lane
- Remove the northbound right-turn lane
- Provide a protected bike lane on each side of the east leg
- Provide a bike box on the east leg and a marked bike crossing
- Provide shared path markings on the east sidewalk south to William Street
- Construct parking bumpouts on each side of the north and south legs

The study additionally recommends implementing an exclusive pedestrian phase (EPP) to the signal timing operations. The study recommends that the City pursue EPP Option 1 as described in Section 4.3.2. While the signal is operating with an exclusive pedestrian phase, vehicle movements will be prohibited. To reduce pedestrian delay and eliminate the potential conflict of pedestrians walking on a prolonged DO NOT WALK indication, the concurrent WALK (recall) phases will remain. A R10-11 "No Turn on Red" sign should be installed facing the westbound and northbound approaches. It was discussed by the project team to test this operation by implementing the timing changes to the signal controllers and installing temporary R10-11 "No Turn on Red" signs. The test case will allow the City to conduct an evaluation on traffic safety and operations for a period of time and make adjustments as necessary. Preliminary analysis determined that the signalized intersection would operate optimally at the following phase splits:

- 90 Second Cycle Length (AM Peak and PM Peak)
 - Exclusive Pedestrian Phase: 23 Seconds in AM Peak and PM Peak
 - State Street Phase: 47 Seconds in AM Peak; 44 Seconds in PM Peak
 - North University Avenue Phase: 20 Seconds in AM Peak; 23 Seconds in PM Peak

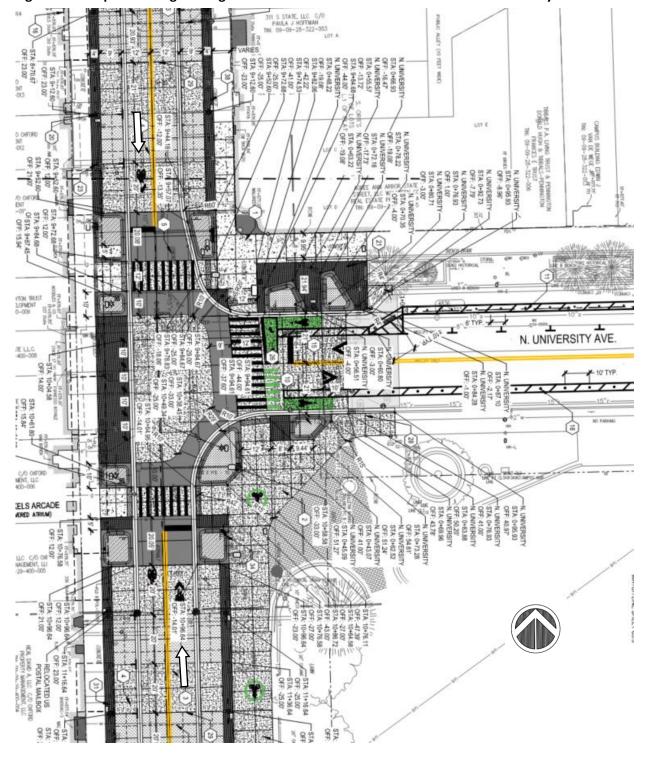

Figure 6-3. Proposed Design Changes at Intersection of State Street and North University Avenue.

6.2.4 State Street and William Street

At the signalized intersection of State Street and William Street, the study recommends implementing the proposed design changes as depicted in **Figure 6-4** and listed below:

- Construct parking bumpouts on each side of the north leg and the east side of the south leg of the intersection
- Bi-directional bikeway crossing east / west on north side of William Street and State Street intersection
- Provide shared path markings on the east sidewalk north to North University Avenue

The study additionally recommends implementing an exclusive pedestrian phase (EPP) to the signal timing operations. The study recommends that the City pursue EPP Option 1 as described in Section 4.3.2. While the signal is operating with an exclusive pedestrian phase, vehicle movements will be prohibited. To reduce pedestrian delay and eliminate the potential conflict of pedestrians walking on a prolonged DO NOT WALK indication, the concurrent WALK (recall) phases will remain. A R10-11 "No Turn on Red" sign should be installed facing the westbound and northbound approaches. It was discussed by the project team to test this operation by implementing the timing changes to the signal controllers and installing temporary R10-11 "No Turn on Red" signs. The test case will allow the City to conduct an evaluation on traffic safety and operations for a period of time and make adjustments as necessary. Preliminary analysis determined that the signalized intersection would operate optimally at the following phase splits:

- 90 Second Cycle Length (AM Peak and PM Peak)
 - o Exclusive Pedestrian Phase: 20 Seconds in AM Peak and PM Peak
 - State Street Phase: 50 Seconds in AM Peak and PM Peak
 - William Street Phase: 20 Seconds in AM Peak and PM Peak

APPENDIX B. SAFETY ANALYSIS

1.0 INTRODUCTION

The City of Ann Arbor Downtown Development Authority (DDA) has developed a Healthy Streets program intended to create a connected network of streets which provide safe and equitable mobility for all users, particularly in the downtown area. Within the downtown, the State Street corridor has been selected for a corridor-wide safety evaluation as described in the present report. A five-year crash analysis between 2016 to 2020 is performed to determine corridor-wide summary statistics such as crash frequency, year of occurrence, type, and severity. Individual intersections are further investigated to provide stakeholders insight into the expected safety impacts garnered by planned and/or potential engineering modifications. The individual Crash Modification Factors (CMFs) for each engineering treatment are applied to the existing crash frequencies to calculate the anticipated change in total crashes.

2.0 CRASH ANALYSIS FOR STATE STREET

To provide an overview of the crash history of State Street from William Street to Washington Street, this analysis includes all of the crash data throughout the study corridor. The crashes are separated into various categories based on the circumstances of each crash, and the corresponding discussions can be used to determine causal factors and corrective action. Figure 1 shows the vehicle crash density, both total and injury crashes only, for each of the intersections on State Street. Figure 2 shows the pedestrian and bicyclist crashes at each intersection.

Figure 1. State Street Vehicle Crash Density Diagram.

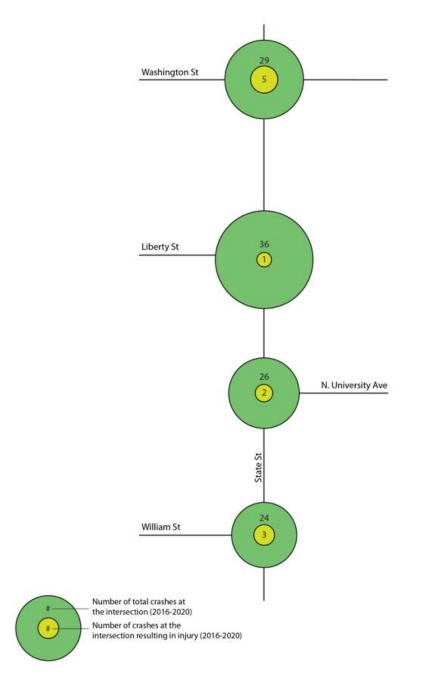

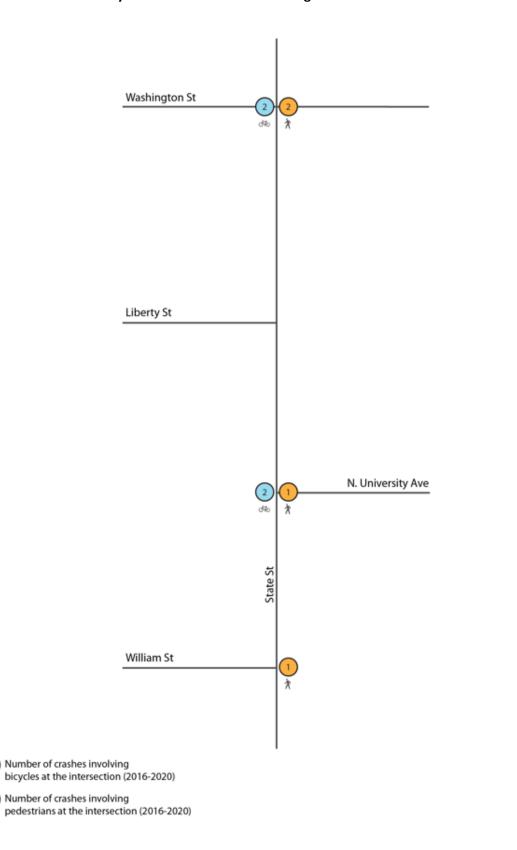

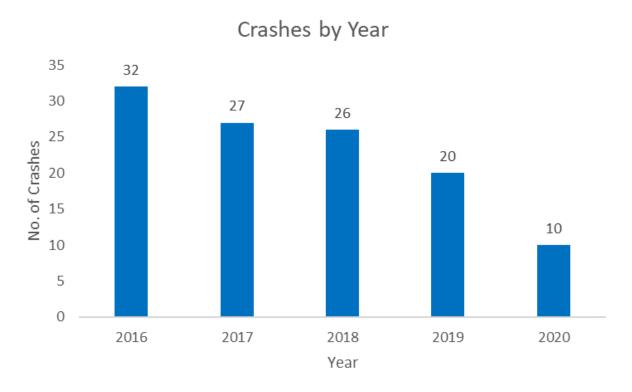

Figure 2. State Street Bicyclist and Pedestrian Crash Diagram.

2.1 TOTAL CRASHES ON STATE STREET

During the five-year study period between January 1, 2016 and December 31, 2020, a total of 115 crashes were reported within the State Street project limits. Of this total, 41.7% of the crashes were sideswipe – same direction, 19.1% were rear end, and 13.0% were backing collisions. Overall, 90.4% of the crashes were property damage only and there were no reported fatalities. Figure 3 displays the number of crashes per year along State Street from 2016 to 2020.

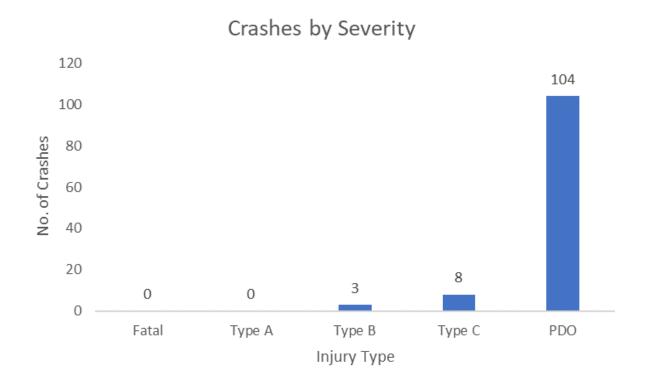

Figure 3. State Street Crashes by Year, 2016 to 2020.

2.2 CRASH SEVERITY

Crash severity, as classified as fatal, injury collisions Type A, B, or C; or property damage only (PDO) crashes, is summarized in Figure 4 for the 5-year study. As shown in Figure 4, 90.4% of the crashes involved property damage only collisions. There were no fatal, no Type A, 3 Type B, and 8 Type C injury crashes. The balance of crashes resulted in PDO.

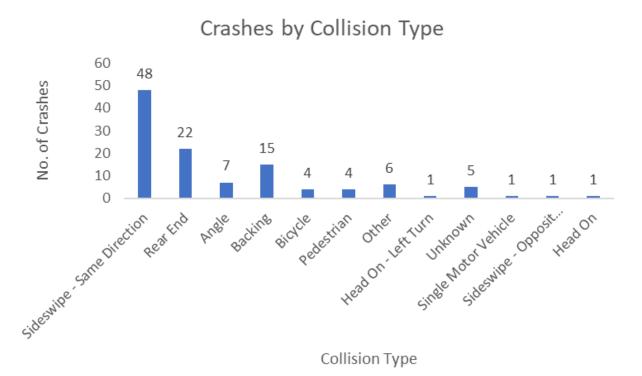

Figure 4 State Street Crashes by Severity, 2016-2020.

2.3 CRASHES BY COLLISION TYPE

As shown in Figure 5, the three predominate types of collisions on State Street were sideswipe/same direction, rear-end, and backing crashes. There are other collision types that also deserve attention. Bicyclist crashes make up 3.5% of the crashes, and pedestrian crashes account for 3.5%. The pedestrian and bicyclist crashes are of particular concern as these groups have a much higher risk of injury. 5 of the 8 bicyclist and pedestrian crashes reported at least one injury.

Figure 5 Crashes by Collision Type on State Street During the Five-year Period.

2.4 CRASHES BY INTERSECTION

The segment of State Street from William Street to Washington Street includes four intersections. The intersection with the highest crash frequency is the intersection with Liberty Street, where 36 crashes occurred in the five-year period. The intersection with Washington Street experienced the highest number and percent of crashes resulting in injury with five crashes.

As part of the Healthy Streets pilot project, motor vehicle, pedestrian, and bicycle volumes were collected at 13 sites throughout the city utilizing a combination of video and tube traffic counters, and specialized bike counters. As shown in Figure 6, observed weekday 2020 traffic volumes were between approximately 16% (before Healthy Streets pilot project) to 23% (after Healthy Streets pilot project) lower than pre-COVID traffic volumes at the State Street count location.

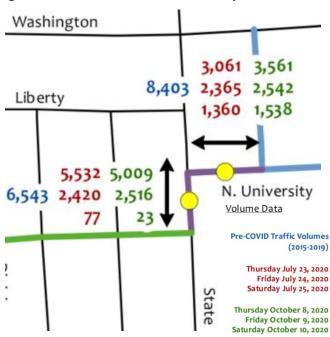

Figure 6 COVID-19 Traffic Volume Comparisons

As shown in Figure 3, the average crash rate between 2016 to 2019 on the State Street study corridor was 46 crashes per year, while only 13 crashes occurred in 2020, resulting in a reduction in the average total crash rate of 72%. Conventional understanding is that crash frequency is directly correlated to traffic volumes, as the potential for crashes is related to motor vehicle and non-motorized user exposure at conflict points. The disparity between the relatively lower reduction in traffic volumes compared to the reduction in crash rate on State Street before and after the COVID-19 pandemic suggests additional factors causing the observed decrease in crashes. One of these factors may be the implementation of leading pedestrian intervals (LPIs) at the William Street, North University Avenue, and Liberty Street intersections on State Street. Thus, at these intersections, the 2020 crash data was removed from the crash modification factors analysis, as described in the next sections of this report.

Crash Modification Factors (CMFs) are used to compute the expected number of crashes after implementing a countermeasure on a road or intersection and are obtained from similar projects and studies. The CMF Clearinghouse website database (http://www.cmfclearinghouse.org/) was used to determine the safety benefits of the intersection treatments and provide an estimate of potential crash reductions or increases at the intersections with proposed modifications. Tables showing these estimates are provided for each intersection where modifications impact the expected number of crashes. Using these CMFs, the proposed modifications for the State Street project area could potentially *decrease* total crashes by up to 7.35 crashes per year.

2.4.2 Crashes at State Street and William Street

As shown in Table 2, 24 crashes occurred at the signalized intersection of State Street and William Street during the five-year period. Seven of these crashes involved rear end crashes, including all three injury crashes. There was also one pedestrian crash at this intersection where a pedestrian was struck in the crosswalk, but no injuries were reported.

Table 2 Crash Frequency at Intersection of State Street and William Street During the Five-year Period.

| Crash Characteristics | No. of Crashes | No. of Crashes / Year | Percentage |
|------------------------------|----------------|-----------------------|------------|
| Rear End | 7 | 1.4 | 29.2 |
| Sideswipe – Same Direction | 6 | 1.2 | 25.0 |
| Backing | 3 | 0.6 | 12.5 |
| Other | 3 | 0.6 | 12.5 |
| Angle | 2 | 0.4 | 8.3 |
| Pedestrian | 1 | 0.2 | 4.2 |
| Head On | 1 | 0.2 | 4.2 |
| Unknown | 1 | 0.2 | 4.2 |
| Total | 24 | 4.8 | 100.0 |
| | | | |
| Injury Type C | 3 | 0.6 | 12.5 |

Table 3 summarizes the crash modification factors (CMFs) which can be applied to the existing crashes as a result of the proposed geometric and operational changes at the intersection. The City of Ann Arbor implemented leading pedestrian intervals (LPIs) for each signal phase prior to 2020. As a result, the three crashes which occurred in 2020 were removed from the CMF analysis, producing an average total crash rate of 5.3 crashes per year. As seen, the proposed countermeasures are expected to produce a net reduction of 2.07 total crashes per year at the intersection of State Street and William Street.

Table 3 CMFs at Intersection of State Street and William Street During the Four-year Period.

| Countermeasure | CMF | CRF (%) |
|--|-------|---------|
| Remove a lane | 1.336 | -33.6% |
| Install pedestrian countdown timer | 0.912 | 8.8% |
| Modify signal phasing (implement a leading pedestrian interval) | 0.90 | 10.0% |
| Install advanced yield or stop markings and signs (R10-15 sign) | 0.886 | 11.4% |
| Traffic calming | 0.68 | 32.0% |
| Increase total change interval (greater than ITE recommended practice) | 0.922 | 7.8% |
| Net change in <i>Total</i> crashes (1.336*0.912*0.90*0.886*0.68*0.922) | 0.609 | 39.1% |

Note: Adding a two-way protected bike lane is expected to reduce bicycle related crashes by 70 percent. Since that crash modification factor is only applied to bicycle crashes, it cannot be combined with the other modification factors.

2.4.3 Crashes at State Street and North University Avenue

As shown in Table 4, 26 crashes occurred at the signalized intersection of State Street and North University Avenue during the five-year period, ten of which were reported as sideswipe-same direction crashes. The following two bicyclist crashes and one pedestrian crash occurred, which accounted for both of the injury crashes reported at this intersection:

- One bicyclist crash occurred when a vehicle turned right from the left lane in order to pass a bus, and as such was unable to see the bicyclist approaching the crosswalk, striking them and resulting in a Type B injury.
- One bicyclist crash occurred without injuries when a person in a parked vehicle opened the door, and a bicyclist was unable to stop and struck the door.
- The pedestrian crash at this intersection resulted in a Type B injury when a turning vehicle struck a pedestrian in the crosswalk.

Table 4 Crash Frequency at Intersection of State Street and North University Avenue During the Five-year Period.

| Crash Characteristics | No. of Crashes | No. of Crashes / Year | Percentage |
|----------------------------|----------------|-----------------------|------------|
| Sideswipe – Same Direction | 10 | 2.0 | 38.5 |
| Rear End | 7 | 1.4 | 26.9 |
| Backing | 4 | 0.8 | 15.4 |
| Bicyclist | 2 | 0.4 | 7.7 |
| Pedestrian | 1 | 0.2 | 3.8 |
| Unknown | 1 | 0.2 | 3.8 |
| Other | 1 | 0.2 | 3.8 |
| Total | 26 | 5.2 | 100.0 |
| | | | |
| Injury Type B | 2 | 0.4 | 7.7 |

Table 5 summarizes the crash modification factors (CMFs) which can be applied to the existing crashes as a result of the proposed geometric and operational changes at the intersection. The City of Ann Arbor implemented leading pedestrian intervals (LPIs) for each signal phase prior to 2020. As a result, the one crash which occurred in 2020 was removed from the CMF analysis, producing an average total crash rate of 6.3 crashes per year. As seen, the proposed countermeasures are expected to produce a net decrease of 2.46 total crashes per year at the intersection of State Street and North University Ave.

Table 5 CMFs at Intersection of State Street and North University Avenue During the Four-year Period.

| | | () |
|--|-------|---------|
| Countermeasure | CMF | CRF (%) |
| Remove a lane | 1.336 | -33.6% |
| Install pedestrian countdown timer | 0.912 | 8.8% |
| Modify signal phasing (implement a leading pedestrian interval) | 0.90 | 10.0% |
| Install advanced yield or stop markings and signs (R10-15 sign) | 0.886 | 11.4% |
| Traffic calming | 0.68 | 32.0% |
| Increase total change interval (greater than ITE recommended practice) | 0.922 | 7.8% |
| Net change in <i>Total</i> crashes (1.336*0.912*0.90*0.886*0.68*0.922) | 0.609 | 39.1% |

Note: Adding a two-way protected bike lane is expected to reduce bicycle related crashes by 70 percent. Since that crash modification factor is only applied to bicycle crashes, it cannot be combined with the other modification factors.

2.4.4 Crashes at State Street and Liberty Street

As shown in Table 6, 36 crashes at the signalized intersection of State Street and Liberty Street during the five-year period. The most prominent crash type was the sideswipe-same direction collision with 19 crashes of this type. One crash resulted in a Type C injury. No crashes involved pedestrians or bicyclists at this intersection.

Table 6 Crash Frequency at Intersection of State Street and Liberty Street During the Five-year Period.

| Crash Characteristics | No. of Crashes | No. of Crashes / Year | Percentage |
|--------------------------------|----------------|-----------------------|------------|
| Sideswipe – Same Direction | 19 | 3.8 | 52.8 |
| Backing | 5 | 1.0 | 13.9 |
| Rear End | 3 | 0.6 | 8.3 |

| Angle | 2 | 0.4 | 5.6 |
| Other | 2 | 0.4 | 5.6 |
| Single Motor Vehicle | 1 | 0.2 | 2.8 |
| Sideswipe – Opposite Direction | 1 | 0.2 | 2.8 |
| Total | 36 | 7.2 | 100.0 |
| | | | |
| Injury Type C | 1 | 0.2 | 2.8 |

Table 7 summarizes the crash modification factors (CMFs) which can be applied to the existing crashes as a result of the proposed geometric and operational changes at the intersection. The City of Ann Arbor implemented leading pedestrian intervals (LPIs) for each signal phase prior to 2020. As a result, the four crashes which occurred in 2020 were removed from the CMF analysis, producing an average total crash rate of 8.0 crashes per year. As seen, the proposed countermeasures are expected to produce a net reduction of 2.82 total crashes per year at the intersection of State Street and Liberty Street.

Table 7 CMFs at Intersection of State Street and Liberty Street During the Four-year Period.

| Countermeasure | CMF | CRF (%) |
|--|-------|---------|
| Remove a left-turn lane on one major-road approach | 1.42 | -42.0% |
| Install pedestrian countdown timer | 0.912 | 8.8% |
| Modify signal phasing (implement a leading pedestrian interval) | 0.90 | 10.0% |
| Install advanced yield or stop markings and signs (R10-15 sign) | 0.886 | 11.4% |
| Traffic calming | 0.68 | 32.0% |
| Increase total change interval (greater than ITE recommended practice) | 0.922 | 7.8% |
| Net change in <i>Total</i> crashes (1.42*0.912*0.90*0.886*0.68*0.922) | 0.647 | 35.3% |

2.4.5 Crashes at State Street and Washington Street

As shown in Table 8, 29 crashes occurred at the signalized intersection of State Street and Washington Street during the five-year period, including 13 classified as sideswipe-same direction collisions. The following two pedestrian crashes and two bicyclist crashes, which accounted for three of the five total injury crashes at this intersection:

- Both bicyclist crashes were recorded as injury crashes, including a Type B injury where the bicyclist turned left in front of a vehicle, and a Type C injury resulted from by a vehicle striking a bicyclist while pulling out from a parking spot.
- One pedestrian crash that resulted in a Type C injury occurred when a turning vehicle struck a
 pedestrian in the crosswalk.
- One pedestrian crash happened when a vehicle struck a pedestrian in the crosswalk at night when they did not see the pedestrian, but no injuries were reported.

Table 8 Crash Frequency at Intersection of State Street and Washington Street During the Five-year Period.

| Crash Characteristics | No. of Crashes | No. of Crashes / Year | Percentage |
|----------------------------|----------------|-----------------------|------------|
| Sideswipe – Same Direction | 13 | 2.6 | 44.8 |
| Rear End | 5 | 1.0 | 17.2 |
| Angle | 3 | 0.6 | 10.3 |
| Backing | 3 | 0.6 | 10.3 |
| Bicyclist | 2 | 0.4 | 6.9 |
| Pedestrian | 2 | 0.4 | 6.9 |
| Head On – Left Turn | 1 | 0.2 | 3.4 |
| Total | 29 | 5.8 | 100.0 |
| | | | |
| Injury Type B | 1 | 0.2 | 3.4 |
| Injury Type C | 4 | 0.8 | 13.8 |

3.0 CONCLUSION

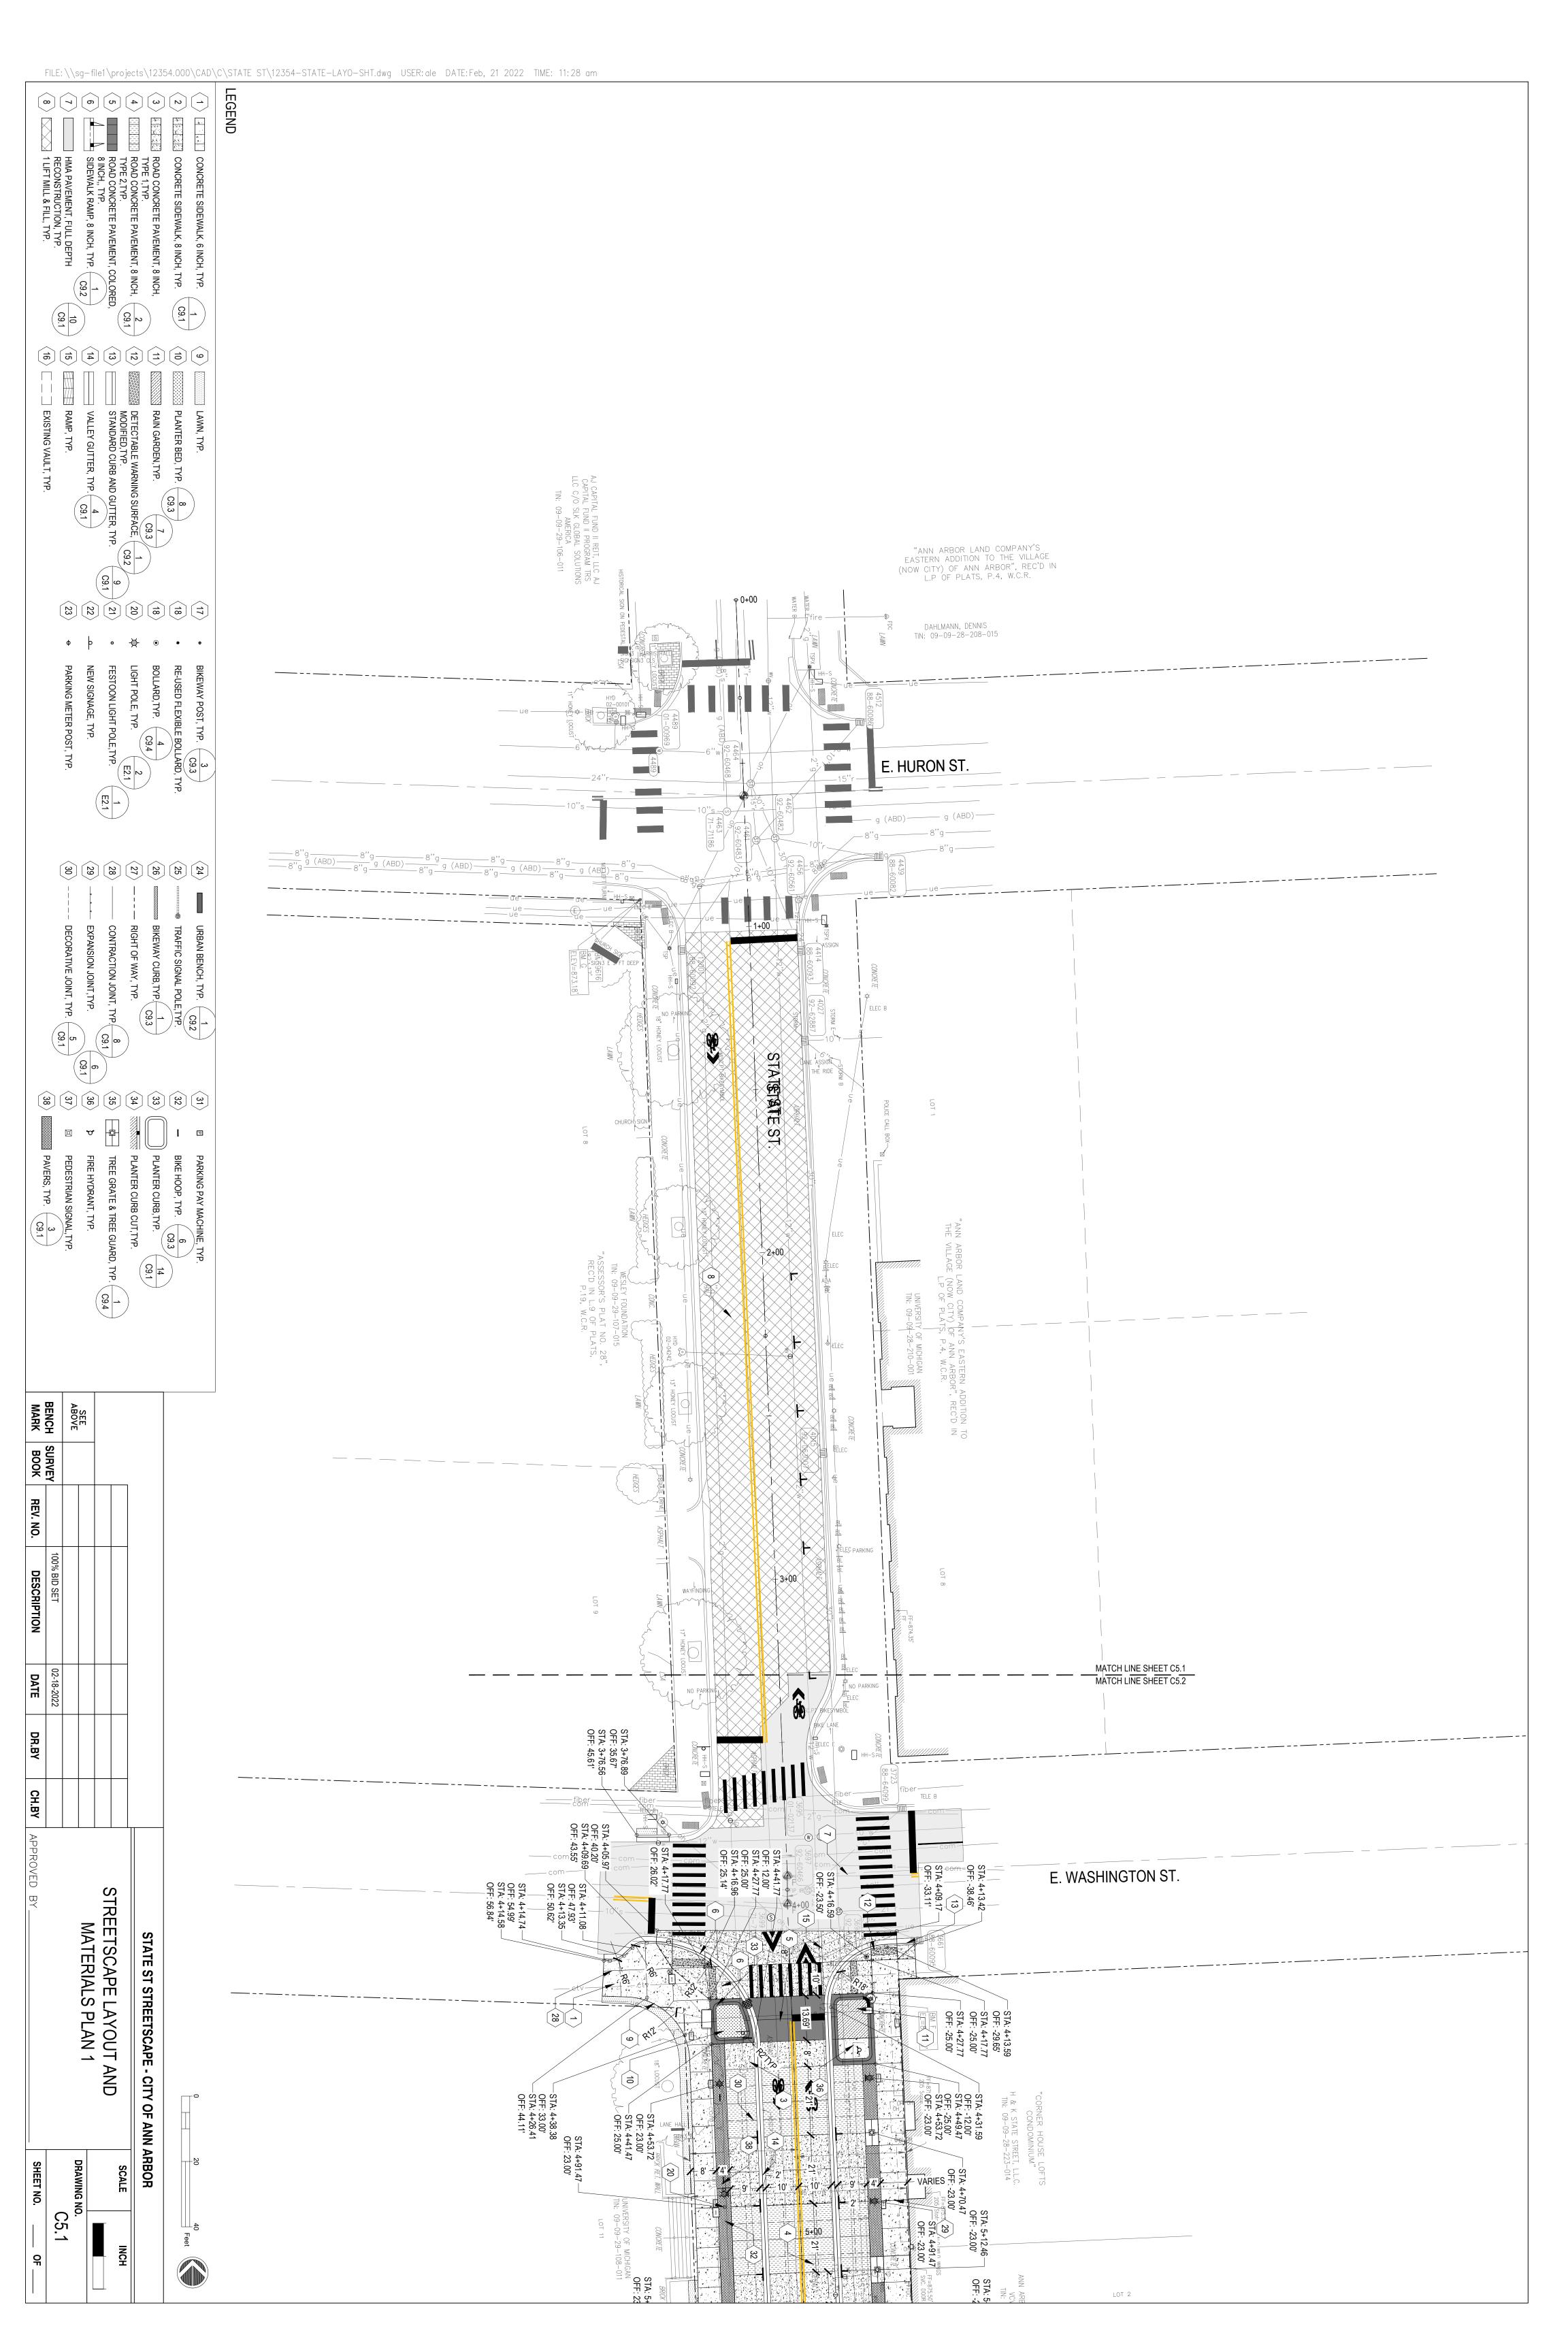

In this report, the crash history between 2016 to 2020 was summarized by frequency, year of occurrence, type, and severity along the State Street corridor in the City of Ann Arbor. The crash history was used to develop a profile which could aid in the selection of targeted engineering countermeasures to improve safety and meet the goals of the City's Healthy Streets program. One of these goals is to promote physical distancing by increasing outdoor space for pedestrian and bicycle travel and connecting critical gaps in the bike network. Based on the crash patterns and known future improvements by the City, various safety treatments, which differ by intersection, were selected as potential countermeasures for crash mitigation analysis. These countermeasures along with their associated Crash Modification Factors (CMFs) are provided in Table 11 below.

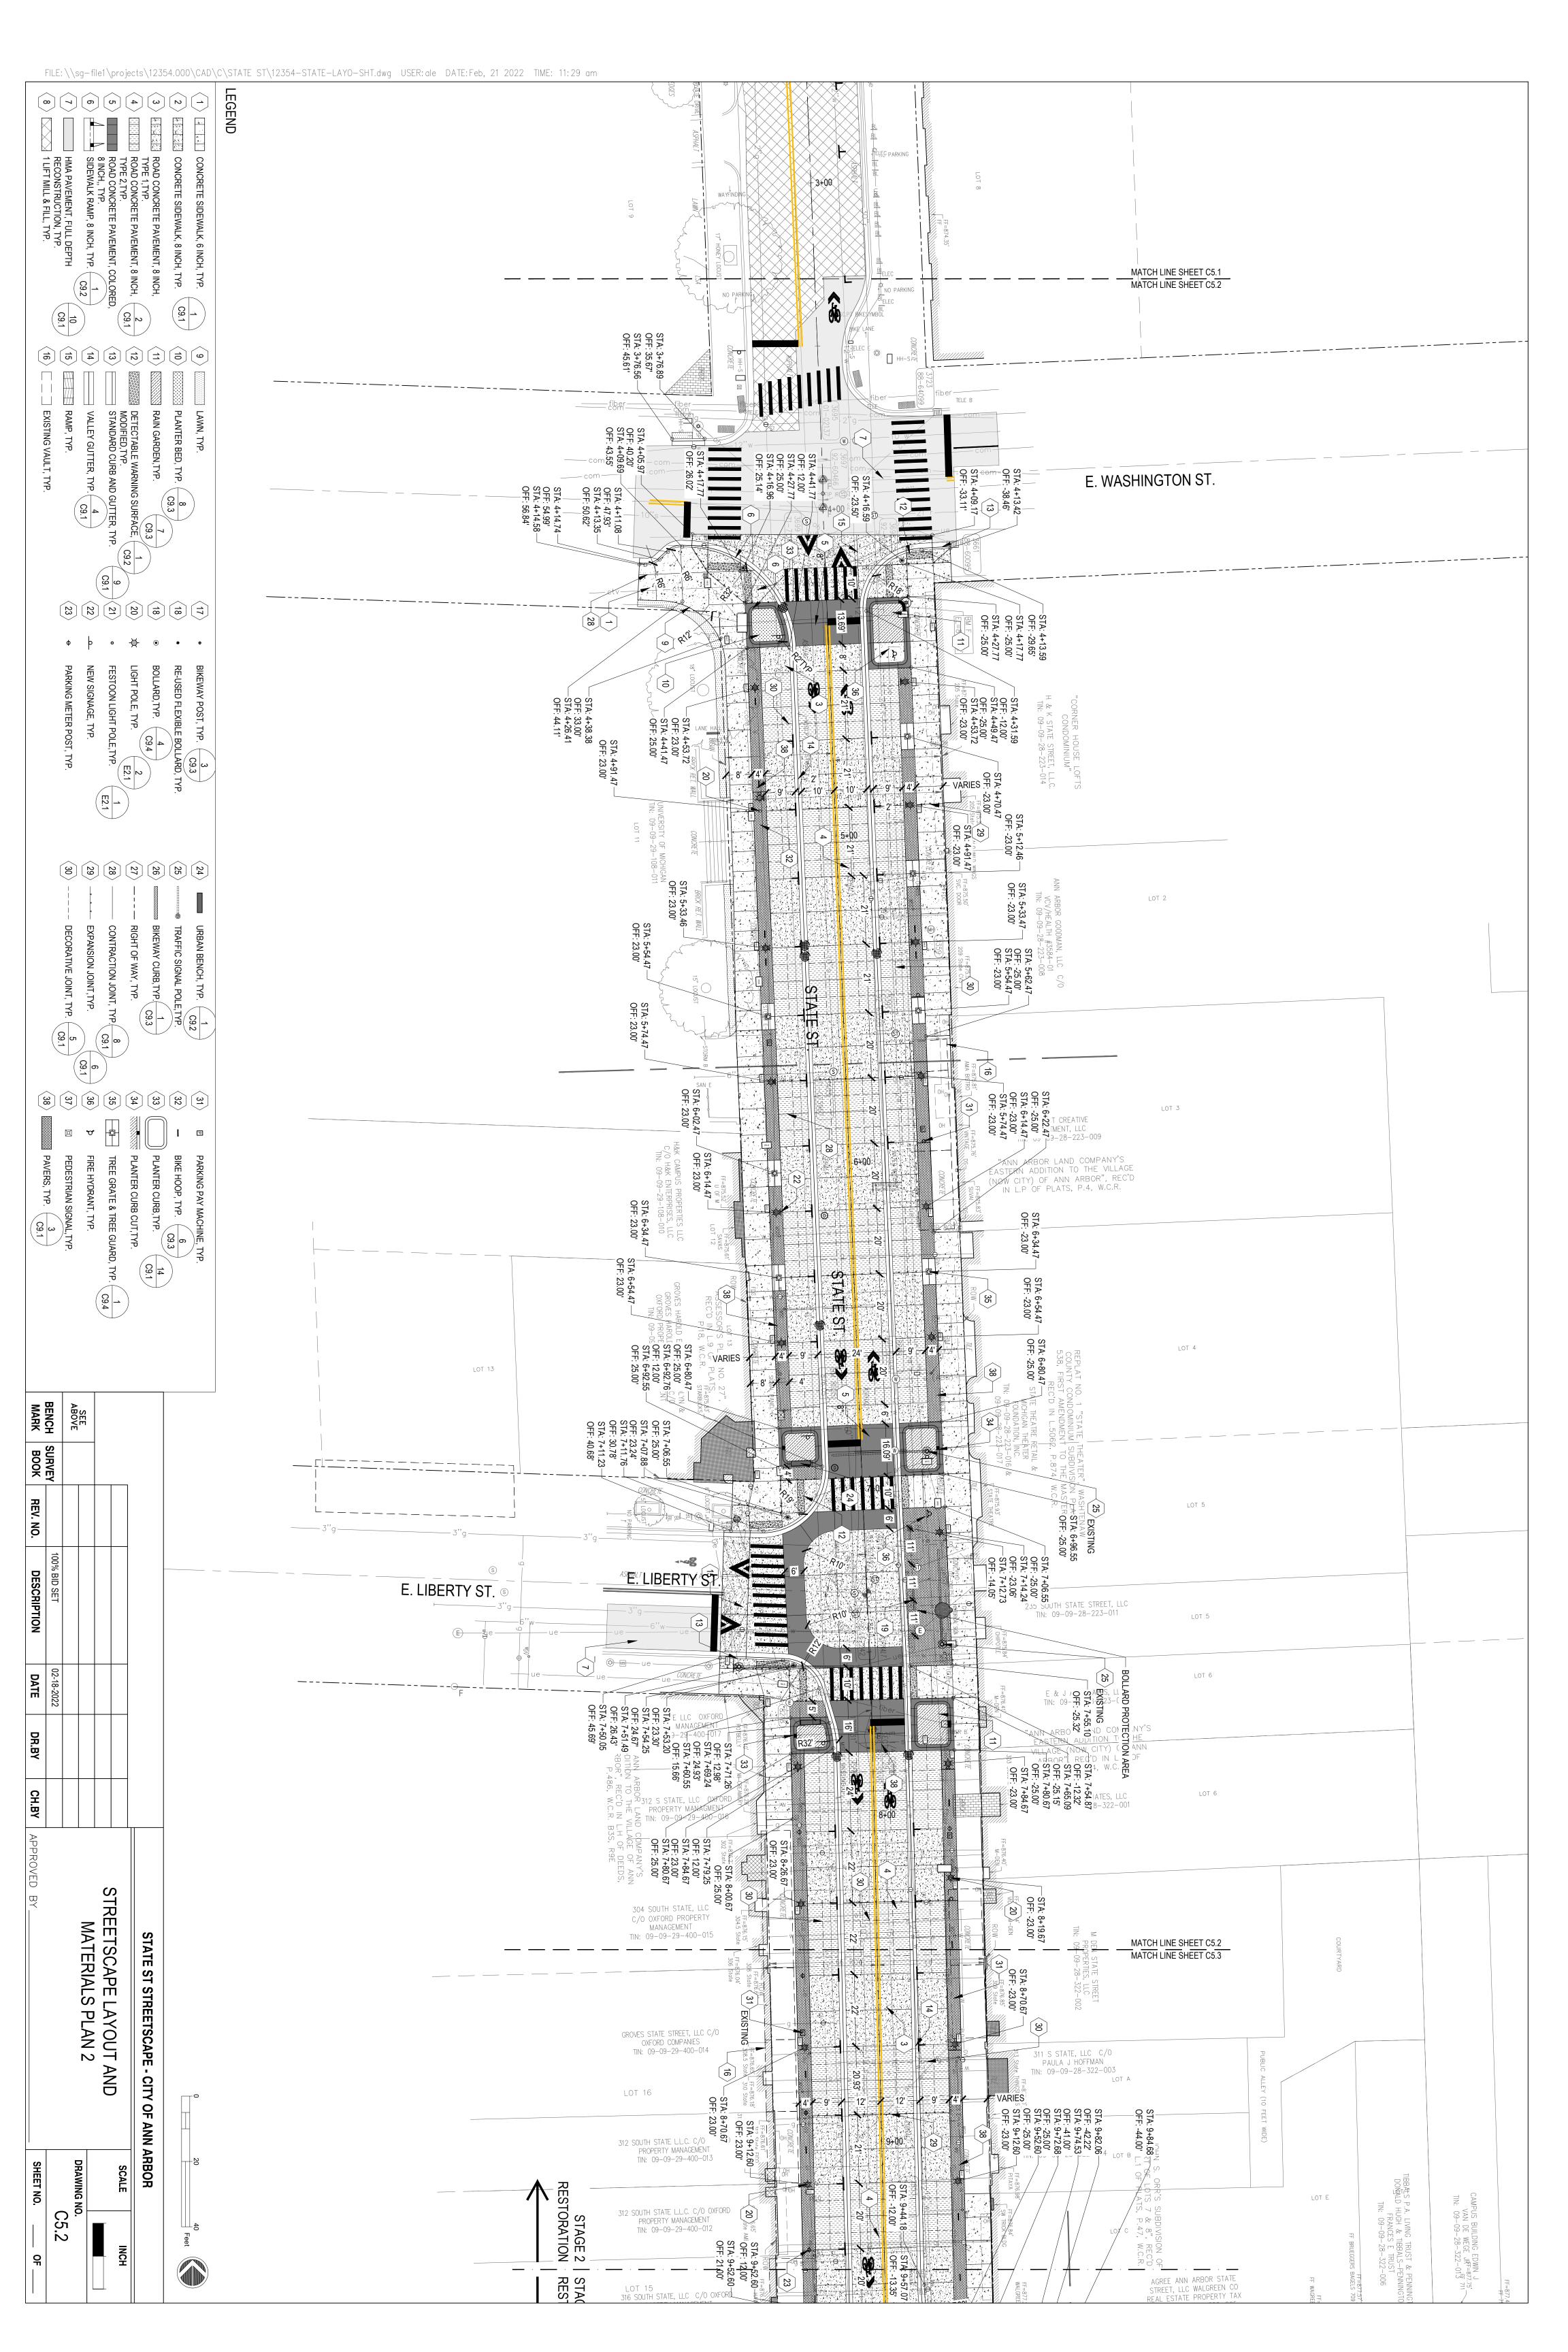

Table 11 Summary of Countermeasures.

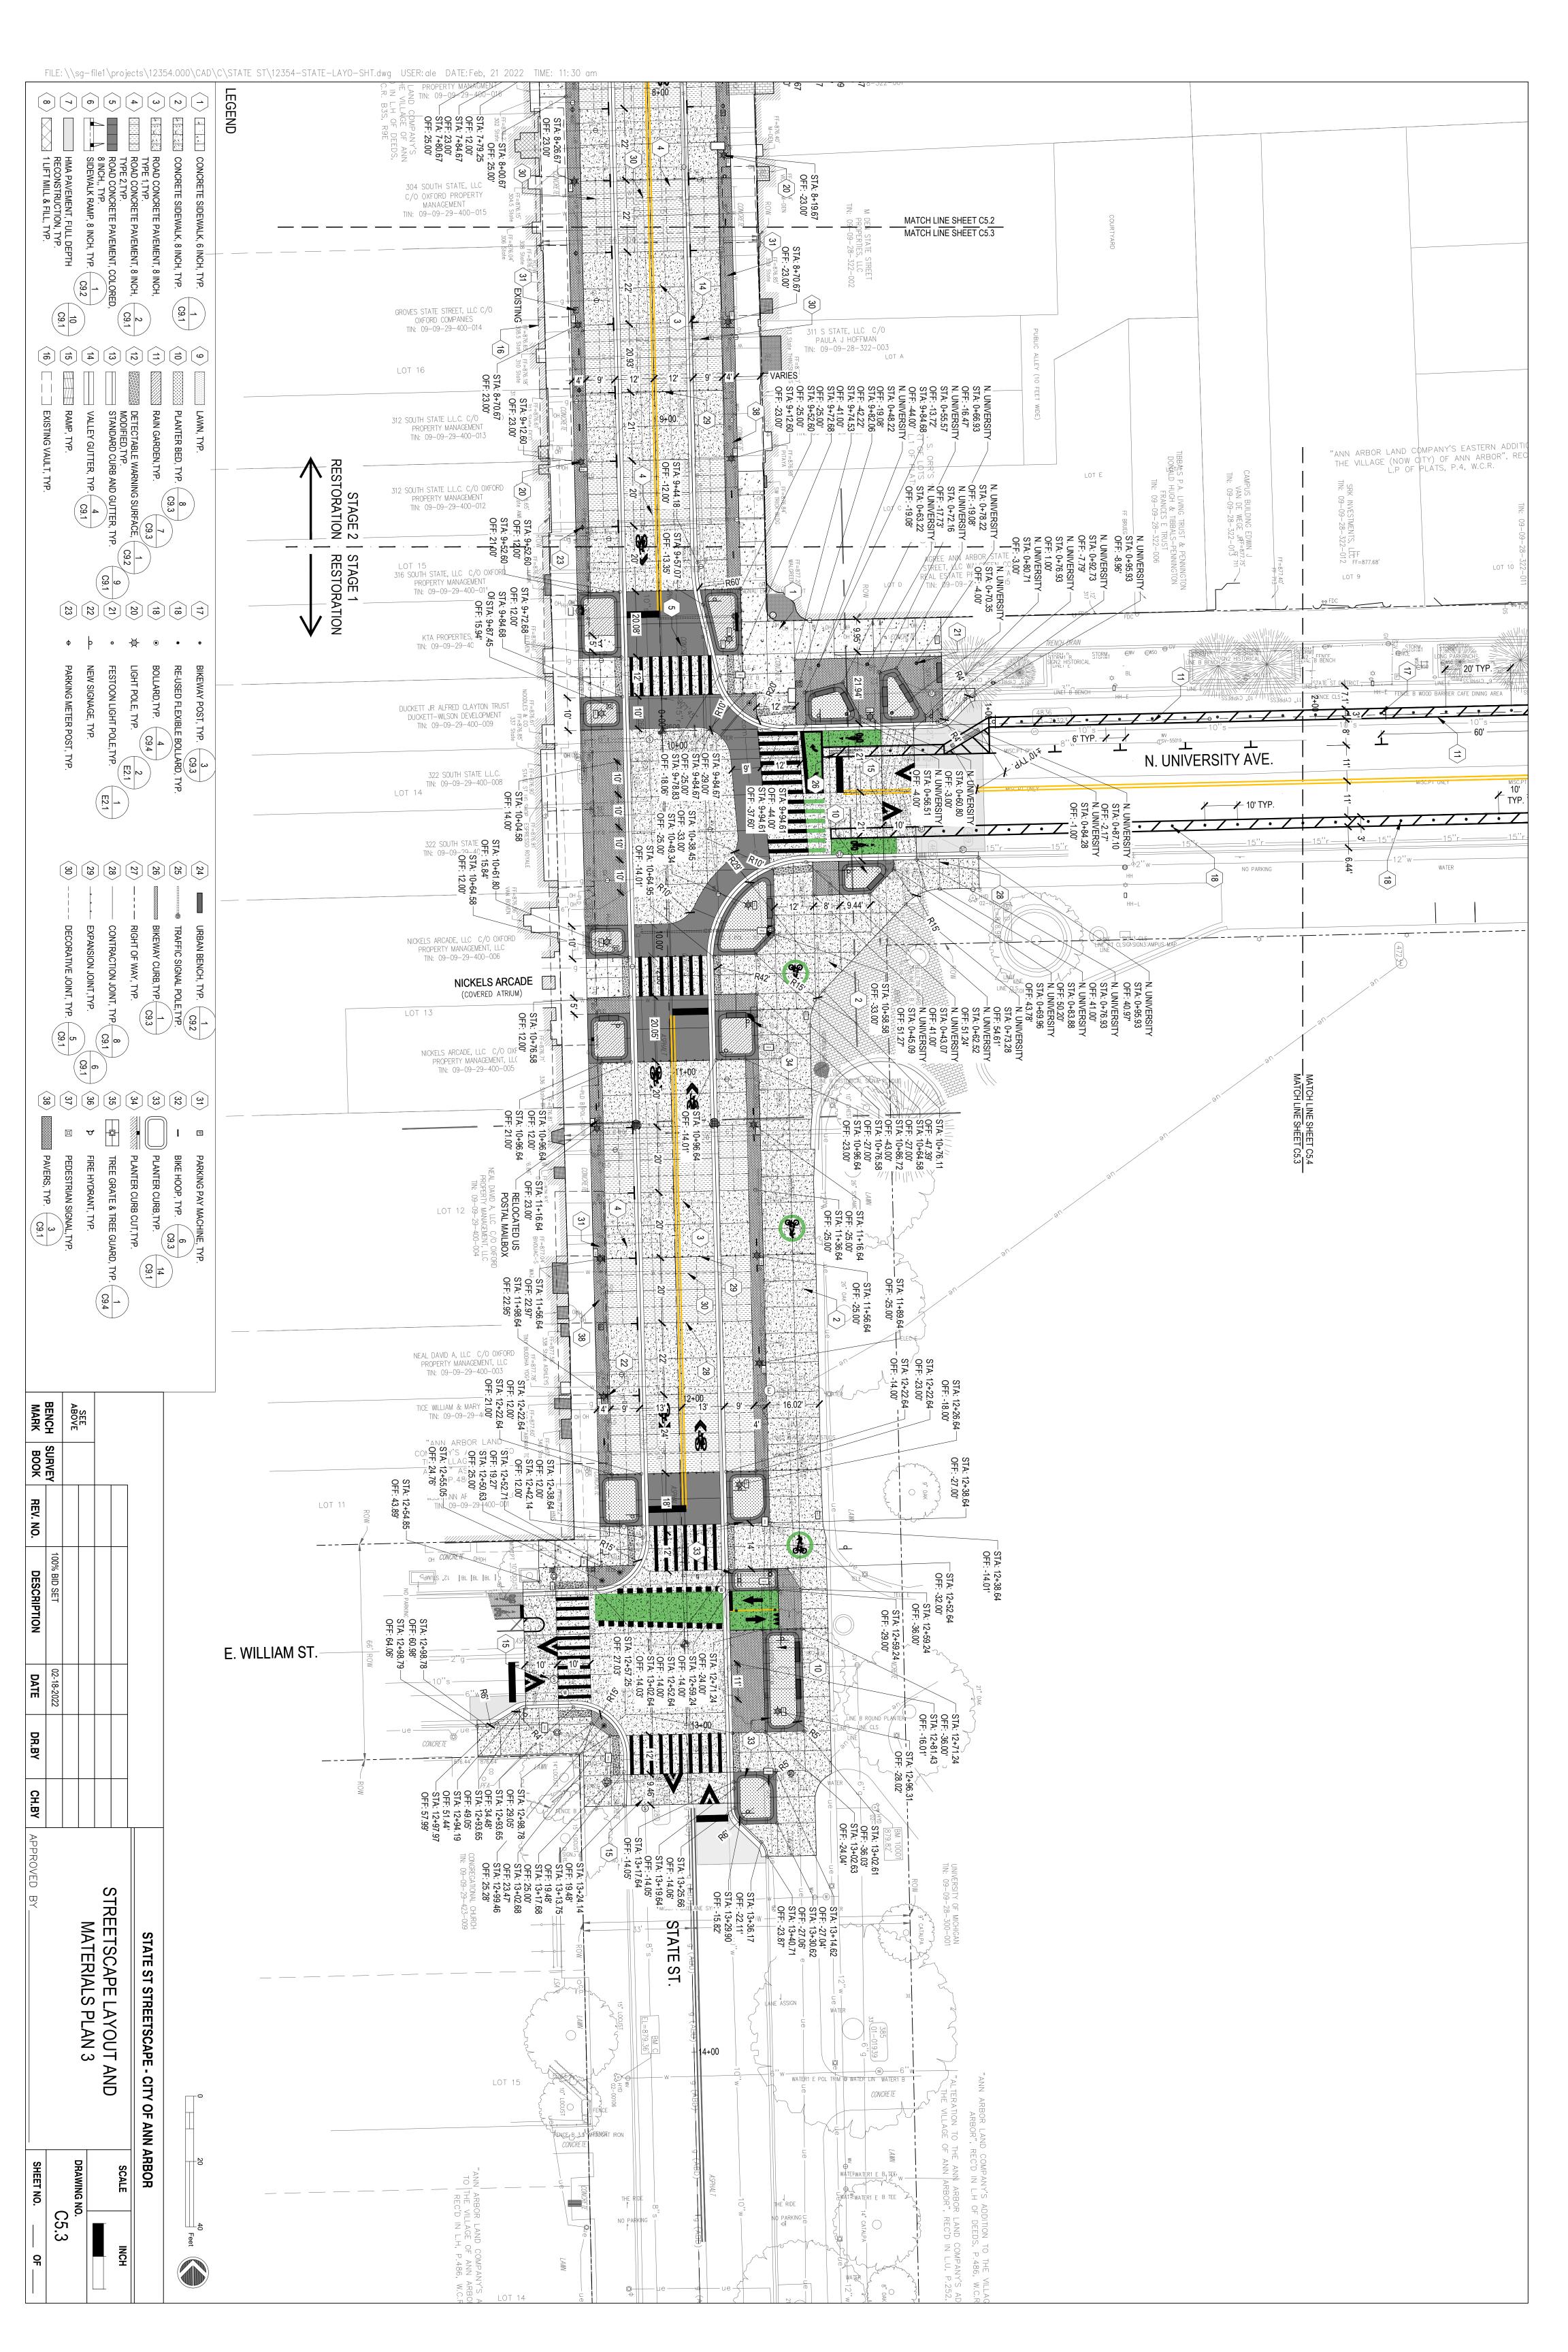

| Countermeasure | CMF | CRF (%) | Crash Type |
|--|-------|---------|---------------|
| Remove a left-turn lane on one major-road approach | 1.42 | -42.0 | All |
| Remove a lane | 1.336 | -33.6 | All |
| Add two-way protected bike lane | 0.3 | 70.0 | Bicyclist |
| Install pedestrian countdown timer | 0.912 | 8.8 | All |
| Modify signal phasing (implement a leading pedestrian interval) | 0.9 | 10.0 | All |
| Install advanced yield or stop markings and signs (R10-15 sign) | 0.886 | 11.4 | All |
| Traffic calming | 0.68 | 32.0 | All |
| Increase total change interval (greater than ITE recommended practice) | 0.922 | 7.8 | All |

On the State Street corridor from William Street to Washington Street, there were a total of 115 crashes reported during the five-year period. No crashes were reported which resulted in a Type A injury or fatality. However, three Type B, and eight Type C injury crashes occurred along the corridor. The predominate crash types involved either a sideswipe – same direction collision, rear end, or backing collision. There were 4 crashes involving a bicyclist and 4 crashes involving a pedestrian. 5 of the 8 bicyclist and pedestrian crashes reported at least one injury. The CMFs for the proposed safety treatments at the four intersections could potentially *reduce* corridor-wide total crashes by up to 7.35 crashes per year. Like the other two corridors under evaluation, implementing a two-way protected bike lane and a leading pedestrian interval at signalized intersections where they are not already present are anticipated to provide the most safety benefit.
